

A QUADRATIC DOUBLE DIRICHLET SERIES II: THE NUMBER FIELD CASE

HENRY TWISS

ABSTRACT. We construct a quadratic double Dirichlet series $Z(s, w)$ built from single variable quadratic Dirichlet L -functions $L(s, \chi)$ over \mathbb{Q} . We prove that $Z(s, w)$ admits meromorphic continuation to the (s, w) -plane and satisfies a group of functional equations.

1. PRELIMINARIES

We present an overview of quadratic Dirichlet L -functions over \mathbb{Q} . We begin with the Riemann zeta-function. The zeta function $\zeta(s)$ is defined as the Dirichlet series or Euler product

$$\zeta(s) = \sum_{m \geq 1} \frac{1}{m^s} = \prod_{p \text{ prime}} \left(1 - \frac{1}{p^s}\right)^{-1},$$

for $\operatorname{Re}(s) > 1$. The second equality is an analytic reformulation of the fundamental theorem of arithmetic. The Riemann zeta function also admits meromorphic continuation to \mathbb{C} with a simple pole at $s = 1$ of residue 1. The functional equation is

$$\pi^{-\frac{s}{2}} \Gamma\left(\frac{s}{2}\right) \zeta(s) = \pi^{-\frac{1-s}{2}} \Gamma\left(\frac{1-s}{2}\right) \zeta(1-s).$$

Now we recall characters on \mathbb{Z} . They are multiplicative functions $\chi : \mathbb{Z} \rightarrow \mathbb{C}$. They form a group under multiplication. The two flavors we will care about are:

- Dirichlet characters: multiplicative functions $\chi_d : \mathbb{Z} \rightarrow \mathbb{C}$ modulo $d \geq 1$ (in that they are d -periodic) and such that $\chi_d(m) = 0$ if $(m, d) > 1$.
- Hilbert characters: The group of characters generated by those that appear in the sign change of reciprocity statements.

The image of a Dirichlet character always lands in the roots of unity. If χ is a Dirichlet character then its conjugate $\bar{\chi}$ is also a Dirichlet character. Moreover, $\bar{\chi}$ is the multiplicative inverse to χ and the Dirichlet characters modulo m form a group under multiplication. This group is always finite and its order is $\phi(d) = |(\mathbb{Z}/d\mathbb{Z})^*|$. Dirichlet characters also satisfy orthogonality relations:

Theorem 1.1 (Orthogonality relations).

(i) For any two Dirichlet characters χ and ψ modulo d ,

$$\frac{1}{\phi(d)} \sum_{a \pmod{d}}' \chi(a) \bar{\psi}(a) = \delta_{\chi, \psi}.$$

(ii) For any $a, b \in (\mathbb{Z}/d\mathbb{Z})^*$,

$$\frac{1}{\phi(d)} \sum_{\chi \pmod{d}} \chi(a) \bar{\chi}(b) = \delta_{a, b}.$$

The Dirichlet characters that are of interest to us are those given by the quadratic residue symbol on \mathbb{Z} . First let us recall this symbol. For any odd prime p and any $m \geq 1$, we define the quadratic residue symbol $\left(\frac{m}{p}\right)$ by

$$\left(\frac{m}{p}\right) \equiv m^{\frac{p-1}{2}} \pmod{p} = \begin{cases} 1 & \text{if } x^2 \equiv m \pmod{p} \text{ is solvable,} \\ -1 & \text{if } x^2 \equiv m \pmod{p} \text{ is not solvable,} \\ 0 & \text{if } m \equiv 0 \pmod{p}. \end{cases}$$

This symbol only depends upon m modulo p and is multiplicative in m . We can extend the quadratic residue symbol multiplicatively in the denominator. If $d = p_1^{e_1} p_2^{e_2} \cdots p_k^{e_k}$ is the prime factorization of d , then we define

$$\left(\frac{m}{d}\right) = \prod_{1 \leq i \leq k} \left(\frac{m}{p_i}\right)^{e_i}.$$

So the quadratic residue symbol now makes sense for any odd $d \geq 1$. We can extend this symbol further and allow $d \geq 1$ to be even. To this end, we define

$$\left(\frac{m}{2}\right) = \begin{cases} 1 & \text{if } m \equiv 1, 7 \pmod{8}, \\ -1 & \text{if } m \equiv 3, 5 \pmod{8}, \\ 0 & \text{if } m \equiv 0 \pmod{2}, \end{cases}$$

and extend $\left(\frac{m}{d}\right)$ multiplicatively in d when d is even. Now the quadratic residue symbol makes sense for any $m, d \geq 1$. Moreover, it is multiplicative in both m and d but no longer depends upon only m modulo d (it also depends upon m modulo 8). In particular,

$$\left(\frac{-1}{d}\right) = \begin{cases} 1 & d \equiv 1 \pmod{4}, \\ -1 & d \equiv 3 \pmod{4}, \\ 0 & d \equiv 0 \pmod{2}, \end{cases} \quad \text{and} \quad \left(\frac{2}{d}\right) = \begin{cases} 1 & d \equiv 1, 7 \pmod{8}, \\ -1 & d \equiv 3, 5 \pmod{8}, \\ 0 & d \equiv 0 \pmod{2}, \end{cases}$$

and if $d \not\equiv 0 \pmod{2}$, we can compactly write

$$\left(\frac{-1}{d}\right) = (-1)^{\frac{d-1}{2}} = \begin{cases} 1 & d \equiv 1 \pmod{4}, \\ -1 & d \equiv 3 \pmod{4}, \end{cases} \quad \text{and} \quad \left(\frac{2}{d}\right) = (-1)^{\frac{d^2-1}{8}} = \begin{cases} 1 & d \equiv 1, 7 \pmod{8}, \\ -1 & d \equiv 3, 5 \pmod{8}. \end{cases}$$

The quadratic residue symbol also admits the following reciprocity law:

Theorem 1.2 (Quadratic reciprocity). *If $d, m \geq 1$, then*

$$\left(\frac{d}{m}\right) = (-1)^{\frac{d^{(2)}-1}{2} \frac{m^{(2)}-1}{2}} \left(\frac{m}{d}\right),$$

where $d^{(2)}$ and $m^{(2)}$ are the parts of d and m relatively prime to 2 respectively.

We can now define the quadratic Dirichlet characters. For any odd square-free $d \in \mathbb{Z}$, define the quadratic Dirichlet character χ_d by the following quadratic residue symbol:

$$\chi_d(m) = \begin{cases} \left(\frac{d}{m}\right) & \text{if } d \equiv 1 \pmod{4}, \\ \left(\frac{4d}{m}\right) & \text{if } d \equiv 2, 3 \pmod{4}. \end{cases}$$

This quadratic Dirichlet character is attached to the quadratic extension $\mathbb{Q}(\sqrt{d})$. We extend χ_d multiplicatively in the denominator so that χ_d makes sense for any odd d . In particular, $\chi_d(m) = \pm 1$ provided d and m are relatively prime and $\chi_d(m) = 0$ if $(m, d) > 1$. Quadratic reciprocity implies that χ_d is a Dirichlet character modulo d if $d \equiv 1 \pmod{4}$ and is a Dirichlet character modulo $4d$ if $d \equiv 2, 3 \pmod{4}$. Indeed, if $d \equiv 1 \pmod{4}$ then $d^{(2)} = d$ and the sign is always 1. If $d \equiv 3 \pmod{4}$, then $d^{(2)} = d$ and the sign is

$\left(\frac{-1}{m}\right)$ which is a character modulo 4. If $d \equiv 2 \pmod{4}$, then $d^{(2)} \equiv 1, 3 \pmod{4}$ and we are reduced to one of the previous two cases. We will also set

$$q(d) = \begin{cases} d & \text{if } d \equiv 1 \pmod{4}, \\ 4d & \text{if } d \equiv 2, 3 \pmod{4}, \end{cases} \quad \text{and} \quad \varepsilon_\chi = \frac{\tau(\chi_d)}{\sqrt{q(d)}},$$

where $\tau(\chi_d)$ is the Gauss sum attached to χ_d . We will also require an associated character. For each χ_m (here we are purposely interchanging the roles of d and m to keep consistency with the latter notation when discussing the double Dirichlet series), we define $\tilde{\chi}_m$ by

$$\tilde{\chi}_m(d) = (-1)^{\frac{m^{(2)}-1}{2} \frac{d^{(2)}-1}{2}} \chi_m(d).$$

Equivalently, $\tilde{\chi}_m(d)$ can be expressed as

$$\tilde{\chi}_m(d) = \begin{cases} \chi_m(d) & \text{if } m \equiv 1, 2 \pmod{4}, \\ \chi_{-1}(d)\chi_m(d) & \text{if } m \equiv 3 \pmod{4}, \end{cases}$$

and it follows that $\tilde{\chi}_m(d)$ is a quadratic Dirichlet character of the same modulus as χ_m . We now discuss the Hilbert characters. We will only need four of them: the quadratic Dirichlet characters modulo 8. They are given as follows:

$$\begin{aligned} \chi_1(m) &= \begin{cases} 1 & \text{if } m \not\equiv 0 \pmod{2}, \\ 0 & \text{if } m \equiv 0 \pmod{2}, \end{cases} & \chi_{-1}(m) &= \begin{cases} 1 & \text{if } m \equiv 1 \pmod{4}, \\ -1 & \text{if } m \equiv 3 \pmod{4}, \\ 0 & \text{if } m \equiv 0 \pmod{2}, \end{cases} \\ \chi_2(m) &= \begin{cases} 1 & \text{if } m \equiv 1, 7 \pmod{8}, \\ -1 & \text{if } m \equiv 3, 5 \pmod{8}, \\ 0 & \text{if } m \equiv 0 \pmod{2}, \end{cases} & \chi_{-2}(m) &= \begin{cases} 1 & \text{if } m \equiv 1, 3 \pmod{8}, \\ -1 & \text{if } m \equiv 5, 7 \pmod{8}, \\ 0 & \text{if } m \equiv 0 \pmod{2}. \end{cases} \end{aligned}$$

In general, we will denote a Hilbert character by χ_a with $a \in \{\pm 1, \pm 2\}$. Moreover, observe that $\chi_a(m) = \tilde{\chi}_a(m)$ for all $a \in \{\pm 1, \pm 2\}$ and any $m \geq 1$. Also, can write

$$\chi_{-1}(m) = \left(\frac{-1}{m}\right) \quad \text{and} \quad \chi_2(m) = \left(\frac{m}{2}\right),$$

and have the relations

$$\chi_{-2}(m) = \chi_{-1}(m)\chi_2(m), \quad \chi_1(m) = \chi_{-1}(m)\chi_{-1}(m), \quad \text{and} \quad \chi_{-1}(m) = \chi_2(m)\chi_{-2}(m).$$

Suppose d is square-free. If $d \equiv 1, 2, 5 \pmod{8}$, then $d^{(2)} \equiv 1 \pmod{4}$ so that the sign in the statement of quadratic reciprocity is 1. If $d \equiv 3, 6, 7 \pmod{8}$, then $d^{(2)} \equiv 3 \pmod{4}$ and the sign is $(-1)^{\frac{m^{(2)}-1}{2}}$. This fact together with the relations for the quadratic characters modulo 8 imply

$$\chi_d(m) = \begin{cases} \chi_m(d) & \text{if } d \equiv 1 \pmod{4}, \\ \chi_{-1}(m)\chi_m(d) & \text{if } d \equiv 3 \pmod{4}, \\ \chi_2(m)\chi_m\left(\frac{d}{2}\right) & \text{if } d \equiv 2 \pmod{8}, \\ \chi_{-2}(m)\chi_m\left(\frac{d}{2}\right) & \text{if } d \equiv 6 \pmod{8}. \end{cases}$$

With the Dirichlet and Hilbert characters introduced, we are ready to discuss the L -functions associated to quadratic Dirichlet characters. We define the L -function $L(s, \chi_d)$ attached to χ_d for square-free d , by a Dirichlet series or Euler product:

$$L(s, \chi_d) = \sum_{m \geq 1} \frac{\chi_d(m)}{m^s} = \prod_{p \text{ prime}} \left(1 - \frac{\chi_d(p)}{p^s}\right)^{-1}.$$

By definition of the quadratic Dirichlet character, $L(s, \chi_d) \ll \zeta(s)$ for $\operatorname{Re}(s) > 1$ so that $L(s, \chi_d)$ is locally absolutely uniformly convergent in this region. $L(s, \chi_d)$ also admits analytic continuation to \mathbb{C} . The completed L -function $L^*(s, \chi_d)$ is defined as

$$L^*(s, \chi_d) = \begin{cases} \pi^{-\frac{s}{2}} \Gamma\left(\frac{s}{2}\right) L(s, \chi_d) & \text{if } \chi_d \text{ is even,} \\ \pi^{-\frac{s}{2}} \Gamma\left(\frac{s+1}{2}\right) L(s, \chi_d) & \text{if } \chi_d \text{ is odd,} \end{cases}$$

and satisfies the functional equation

$$L^*(s, \chi_d) = \begin{cases} \varepsilon_\chi q(d)^{\frac{1}{2}-s} L^*(1-s, \chi_d) & \text{if } \chi_d \text{ is even,} \\ -\varepsilon_\chi q(d)^{\frac{1}{2}-s} L^*(1-s, \chi_d) & \text{if } \chi_d \text{ is odd.} \end{cases}$$

Note that the gamma factors depend upon the parity of χ_d . This is the root cause of an important technical issue later when deriving functional equations for the quadratic double Dirichlet series. Analogously, the Dirichlet L -function $L(s, \tilde{\chi}_m)$ attached to $\tilde{\chi}_m$ for square-free m is defined by a Dirichlet series or Euler product:

$$L(s, \tilde{\chi}_m) = \sum_{d \geq 1} \frac{\tilde{\chi}_m(d)}{d^s} = \prod_{p \text{ prime}} \left(1 - \frac{\tilde{\chi}_m(p)}{p^s}\right)^{-1}.$$

As for $L(s, \chi_m)$, $L(s, \tilde{\chi}_m) \ll \zeta(s)$ for $\operatorname{Re}(s) > 1$ so that $L(s, \tilde{\chi}_m)$ is locally absolutely uniformly convergent in this region. Moreover, $L(s, \tilde{\chi}_m)$ admits analytic continuation to \mathbb{C} and the completed L -function $L^*(s, \tilde{\chi}_m)$ is defined as

$$L^*(s, \tilde{\chi}_m) = \begin{cases} \pi^{-\frac{s}{2}} \Gamma\left(\frac{s}{2}\right) L(s, \tilde{\chi}_m) & \text{if } \tilde{\chi}_m \text{ is even,} \\ \pi^{-\frac{s}{2}} \Gamma\left(\frac{s+1}{2}\right) L(s, \tilde{\chi}_m) & \text{if } \tilde{\chi}_m \text{ is odd,} \end{cases}$$

and satisfies the functional equation

$$L^*(s, \tilde{\chi}_m) = \begin{cases} \varepsilon_{\tilde{\chi}} q(m)^{\frac{1}{2}-s} L^*(1-s, \tilde{\chi}_m) & \text{if } \tilde{\chi}_m \text{ is even,} \\ -\varepsilon_{\tilde{\chi}} q(m)^{\frac{1}{2}-s} L^*(1-s, \tilde{\chi}_m) & \text{if } \tilde{\chi}_m \text{ is odd.} \end{cases}$$

Remark 1.1. *The definitions for $L(s, \chi_d)$, $L^*(s, \chi_d)$, $L(s, \tilde{\chi}_m)$, and $L^*(s, \tilde{\chi}_m)$ work perfectly well even when d and m are not square-free (however the functional equations do not hold). We purposely do not define these L -functions, yet, for d and m not necessarily square-free.*

THE QUADRATIC DOUBLE DIRICHLET SERIES

We will now define the quadratic double Dirichlet series $Z(s, w)$. For any integer $d \geq 1$, write $d = d_0 d_1^2$ where d_0 is square-free. Equivalently, d_0 is the square-free part of d and $\frac{d}{d_0}$ is a perfect square. The **quadratic double Dirichlet series** $Z(s, w)$ is defined as

$$Z(s, w) = \sum_{d \text{ odd}} \frac{L^{(2)}(s, \chi_{d_0}) Q_{d_0 d_1^2}(s)}{d^w},$$

where the superscript (2) indicates that the local factor at 2 has been removed, $Q_{d_0 d_1^2}(s)$ is the **correction polynomial** defined by

$$Q_{d_0 d_1^2}(s) = \sum_{e_1 e_2 | d_1} \mu(e_1) \chi_{d_0}(e_1) e_1^{-s} e_2^{1-s} = \sum_{e_1 e_2 e_3 = d_1} \mu(e_1) \chi_{d_0}(e_1) e_1^{-s} e_2^{1-s},$$

and μ is the usual Möbius function. For $\operatorname{Re}(s) > 1$, there is the trivial estimate

$$Q_{d_0 d_1^2}(s) \ll \sum_{e_1 e_2 | d_1} 1 \ll \sigma_0(d_1)^2 \ll_\varepsilon d_1^{2\varepsilon} \ll_\varepsilon d^\varepsilon,$$

for any $\varepsilon > 0$. As $L(s, \chi_{d_0}) \ll 1$ for $\operatorname{Re}(s) > 1$, $Z(s, w)$ is locally absolutely uniformly convergent in the region $\Lambda = \{(s, w) \in \mathbb{C}^2 : \operatorname{Re}(s) > 1, \operatorname{Re}(w) > 1\}$. It will also be necessary to consider quadratic double

Dirichlet series twisted by a pair of Hilbert characters χ_{a_1} and χ_{a_2} . The **quadratic double Dirichlet series** $Z_{a_1, a_2}(s, w)$ twisted by χ_{a_1} and χ_{a_2} is defined as

$$Z_{a_1, a_2}(s, w) = \sum_{d \text{ odd}} \frac{L^{(2)}(s, \chi_{a_1 d_0}) \chi_{a_2}(d) Q_{d_0 d_1^2}(s, \chi_{a_1})}{d^w},$$

where $Q_{d_0 d_1^2}(s, \chi_{a_1})$ is the **correction polynomial** twisted by χ_{a_1} defined by

$$Q_{d_0 d_1^2}(s, \chi_{a_1}) = \sum_{e_1 e_2 | d_1} \mu(e_1) \chi_{a_1 d_0}(e_1) e_1^{-s} e_2^{1-2s} = \sum_{e_1 e_2 e_3 = d_1} \mu(e_1) \chi_{a_1 d_0}(e_1) e_1^{-s} e_2^{1-2s},$$

and μ is the usual Möbius function. By definition of the Hilbert characters, we have the analogous bound $Q_{d_0 d_1^2}(s, \chi_{a_1}) \ll d_\varepsilon$ so that $Z_{a_1, a_2}(s, w)$ converges locally absolutely uniformly in the same region as $Z(s, w)$ does. In particular, $Z(s, w) = Z_{1, 1}(s, w)$.

THE INTERCHANGE

As defined, $Z_{a_1, a_2}(s, w)$ is a sum of L -functions, and hence Euler products, in s . We will prove an interchange formula for $Z_{a_1, a_2}(s, w)$ which will show that it can be expressed as a sum of L -functions in w . That is, we want the variables s and w to change places. Precisely:

Theorem 1.3 (Interchange). *Wherever $Z_{a_1, a_2}(s, w)$ converges locally absolutely uniformly,*

$$Z_{a_1, a_2}(s, w) = \sum_{d \text{ odd}} \frac{L^{(2)}(s, \chi_{a_1 d_0}) \chi_{a_2}(d) Q_{d_0 d_1^2}(s, \chi_{a_1})}{d^w} = \sum_{m \text{ odd}} \frac{L^{(2)}(w, \tilde{\chi}_{a_2 m_0}) \tilde{\chi}_{a_1}(m) Q_{m_0 m_1^2}(w, \tilde{\chi}_{a_2})}{m^s}.$$

Proof. Only the second equality needs to be proved. To do this, first expand the L -function $L^{(2)}(s, \chi_{a_1 d_0})$ and polynomial $Q_{d_0 d_1^2}(s, \chi_{a_1})$ to get

$$\begin{aligned} Z(s, w) &= \sum_{d \text{ odd}} \frac{L(s, \chi_{a_1 d_0}) \chi_{a_2}(d) Q_{d_0 d_1^2}(s, \chi_{a_1})}{d^w} \\ &= \sum_{d \text{ odd}} \left(\sum_{m \text{ odd}} \chi_{a_1 d_0}(m) m^{-s} \right) \left(\sum_{e_1 e_2 | d_1} \mu(e_1) \chi_{a_1 d_0}(e_1) e_1^{-s} e_2^{1-2s} \right) \chi_{a_2}(d) d^{-w} \\ &= \sum_{m, d \text{ odd}} \sum_{e_1 e_2 | d_1} \mu(e_1) \chi_{a_2}(d) \chi_{a_1 d_0}(m e_1) e_1^{-s} e_2^{1-2s} m^{-s} d^{-w}. \end{aligned}$$

Now $\chi_{a_1 d_0}(m e_1) = 0$ unless $(d_0, m e_1) = 1$. We make this restriction on the sum giving

$$\sum_{m, d \text{ odd}} \sum_{\substack{e_1 e_2 | d_1 \\ (d_0, m e_1) = 1}} \mu(e_1) \chi_{a_2}(d) \chi_{a_1 d_0}(m e_1) e_1^{-s} e_2^{1-2s} m^{-s} d^{-w}.$$

Making the change of variables $m e_1 \rightarrow m$ yields

$$\sum_{d \text{ odd}} \sum_{m \text{ odd}} \sum_{\substack{e_1 e_2 | d_1 \\ e_1 | m \\ (d_0, m) = 1}} \mu(e_1) \chi_{a_2}(d) \chi_{a_1 d_0}(m) e_2^{1-2s} m^{-s} d^{-w}.$$

For fixed $d = d_0 d_1^2$ and e_2 , the subsum over m and e_1 is

$$\sum_{\substack{m \text{ odd} \\ e_1 | m}} \sum_{\substack{e_1 | \frac{d_1}{e_2} \\ (d_0, m) = 1}} \mu(e_1) \chi_{a_1 d_0}(m) m^{-s} = \sum_{\substack{m \text{ odd} \\ (d_0, m) = 1}} \chi_{a_1 d_0}(m) m^{-s} \left(\sum_{e_1 | \left(\frac{d_1}{e_2}, m \right)} \mu(e_1) \right).$$

The inner sum over e_1 of the Möbius function vanishes unless $\left(\frac{d_1}{e_2}, m\right) = 1$ in which case it is 1. Therefore the triple sum above becomes

$$\sum_{m, d \text{ odd}} \sum_{\substack{e_2 | d_1 \\ \left(\frac{d_0 d_1}{e_2}, m\right) = 1}} \chi_{a_2}(d) \chi_{a_1 d_0}(m) e_2^{1-2s} m^{-s} d^{-w}.$$

Making the change of variables $d \rightarrow de_2^2$, the condition $\left(\frac{d_0 d_1}{e_2}, m\right) = 1$ becomes $(d_0 d_1, m) = 1$ which is equivalent to $(d, m) = 1$. Moreover, $\chi_{a_2}(de_2^2) = \chi_{a_2}(d)$. Altogether, we obtain

$$\sum_{\substack{m, d \text{ odd} \\ (d, m) = 1}} \sum_{e_2} \chi_{a_2}(d) \chi_{a_1 d_0}(m) e_2^{1-2s-2w} m^{-s} d^{-w}.$$

Writing $m = m_0 m_1^2$ analogously as for d , quadratic reciprocity implies $\chi_{d_0}(m) = \tilde{\chi}_m(d_0) = \tilde{\chi}_{m_0}(d)$ where the last equality holds because $(d, m) = 1$ and both d_0 and m_0 differ from d and m respectively by perfect squares. As $\chi_{a_1}(m) = \tilde{\chi}_{a_1}(m)$ and $\chi_{a_2}(d) = \tilde{\chi}_{a_2}(d)$, the previous fact implies $\chi_{a_2}(d) \chi_{a_1 d_0}(m) = \tilde{\chi}_{a_1}(m) \tilde{\chi}_{a_2 m_0}(d)$ and so our expression becomes

$$\sum_{\substack{d, m \geq 1 \\ (d, m) = 1}} \sum_{e_2} \tilde{\chi}_{a_1}(m) \tilde{\chi}_{a_2 m_0}(d) e_2^{1-2s-2w} m^{-s} d^{-w}.$$

But now we can reverse the argument with the roles of d , m , χ_{a_1} , and χ_{a_2} interchanged respectively, but with $\tilde{\chi}_{a_1}$ and $\tilde{\chi}_{a_2}$, to obtain

$$Z(s, w) = \sum_{m \geq 1} \frac{L(w, \tilde{\chi}_{a_2 m_0}) \tilde{\chi}_{a_1}(m) Q_{m_0 m_1^2}(w, \tilde{\chi}_{a_2})}{m^s}.$$

□

Note that the interchange is not completely symmetric because of the characters $\tilde{\chi}_{a_2 m_0}$, $\tilde{\chi}_{a_1}$, and $\tilde{\chi}_{a_2}$ in the second expression for $Z_{a_1, a_2}(s, w)$. This is due to the fact that reciprocity is not perfect. In even more general settings the correction polynomials in w need not be equal to those in s .

WEIGHTING TERMS

We will now study the coefficients of $Z_{a_1, a_2}(s, w)$ expanded in s and w . By expanding $L(s, \chi_{a_1 d_0}) Q_{d_0 d_1^2}(s, \chi_{a_1})$ in the numerator of $Z_{a_1, a_2}(s, w)$, we can write

$$Z_{a_1, a_2}(s, w) = \sum_{d \geq 1} \frac{L(s, \chi_{a_1 d_0}) \chi_{a_2}(d) Q_{d_0 d_1^2}(s, \chi_{a_1})}{d^w} = \sum_{d, m \geq 1} \frac{\chi_{a_1 d_0}(\hat{m}) \chi_{a_2}(d) a(m, d)}{m^s d^w},$$

where \hat{m} is the part of m relatively prime to d_0 and the **weighting coefficient** $a(m, d)$ is given by

$$a(m, d) = \sum_{\substack{e_1 e_2^2 e_3 = m \\ e_1 e_2 | d_1 \\ (d_0, e_1 e_3) = 1}} \mu(e_1) e_2.$$

To see this, the coefficient of $m^{-s}d^{-w}$ in the definition of $Z_{a_1,a_2}(s, w)$ is

$$\begin{aligned} \chi_{a_2}(d) \sum_{\substack{e_1 e_2^2 e_3 = m \\ e_1 e_2 | d_1}} \mu(e_1) \chi_{a_1 d_0}(e_1 e_3) e_2 &= \chi_{a_2}(d) \sum_{\substack{e_1 e_2^2 e_3 = m \\ e_1 e_2 | d_1 \\ (d_0, e_1 e_3) = 1}} \mu(e_1) \chi_{a_1 d_0}(e_1 e_3) e_2 \\ &= \chi_{a_1 d_0}(\widehat{m}) \chi_{a_2}(d) \sum_{\substack{e_1 e_2^2 e_3 = m \\ e_1 e_2 | d_1 \\ (d_0, e_1 e_3) = 1}} \mu(e_1) e_2 \\ &= \chi_{a_1 d_0}(\widehat{m}) \chi_{a_2}(d) a(m, d), \end{aligned}$$

where the first equality holds because $\chi_{d_0}(e_1 e_3) = 0$ unless $(d_0, e_1 e_3) = 1$ and the second equality holds because if $(d_0, e_1 e_3) = 1$, \widehat{m} differs from $e_1 e_3$ by a perfect square (the divisors of which belong to (d_0, e_2)) and so $\chi_{d_0}(e_1 e_3) = \chi_{d_0}(\widehat{m})$.

Remark 1.2. Also, $a(m, d) = 0$ unless $m = e_1 e_2^2 e_3$ with $(d_0, e_1 e_3) = 1$ and $e_1 e_2^2 \mid d_1$.

We will define $L(s, \chi_{a_1 d})$ to be the Dirichlet series given by

$$L(s, \chi_{a_1 d}) = L(s, \chi_{a_1 d_0}) Q_{d_0 d_1^2}(s, \chi_{a_1}) = \sum_{m \geq 1} \frac{\chi_{a_1 d_0}(\widehat{m}) a(m, d)}{m^s}.$$

In particular, $L(s, \chi_d)$ now makes sense for d not necessarily square-free and this definition agrees with the former when d is square-free. Moreover, we have the representation

$$Z_{a_1, a_2}(s, w) = \sum_{d \geq 1} \frac{\chi_{a_2}(d) L(s, \chi_{a_1 d})}{d^w}.$$

If we perform the same procedure to the interchange, then

$$Z_{a_1, a_2}(s, w) = \sum_{m \geq 1} \frac{L(w, \widetilde{\chi}_{a_2 m_0}) \widetilde{\chi}_{a_1}(m) Q_{m_0 m_1^2}(w, \widetilde{\chi}_{a_2})}{m^s} = \sum_{d, m \geq 1} \frac{\widetilde{\chi}_{a_2 m_0}(\widehat{d}) \widetilde{\chi}_{a_1}(m) a(d, m)}{m^s d^w},$$

where \widehat{d} is the part of d relatively prime to m_0 . Analogously, we define $L(w, \widetilde{\chi}_{a_2 m})$ to be the Dirichlet series given by

$$L(w, \widetilde{\chi}_{a_2 m}) = L(w, \widetilde{\chi}_{a_2 m_0}) Q_{m_0 m_1^2}(w, \widetilde{\chi}_{a_2}) = \sum_{d \geq 1} \frac{\widetilde{\chi}_{a_2 m_0}(\widehat{d}) a(d, m)}{d^w},$$

so that

$$Z_{a_1, a_2}(s, w) = \sum_{m \geq 1} \frac{\widetilde{\chi}_{a_1}(m) L(w, \widetilde{\chi}_{a_2 m})}{m^s}.$$

We now investigate the structure of the weighting coefficients $a(m, d)$. Their structure controls the majority of the information about both the double Dirichlet series and the correction polynomials. We first show that the weighting coefficients possess a multiplicativity property:

Proposition 1.1. We have $a(m, 1) = a(1, d) = 1$ and

$$a(m, d) = \prod_{\substack{p^\alpha \parallel m \\ p^\beta \parallel d}} a(p^\alpha, p^\beta).$$

Proof. From the definition of the weighting coefficients, $a(m, 1) = a(1, d) = 1$. We will prove multiplicativity in m and then in d . Letting $m = m' p^\alpha$, we must show

$$a(m, d) = a(m', d) a(p^\alpha, d).$$

To accomplish this, for $e_1 e_2^2 e_3 = m$, let $e_1 = c_1 d_1$, $e_2 = c_2 d_2$, and $e_3 = c_3 d_3$ with $c_1, c_2, c_3 \mid m'$ and $d_1, d_2, d_3 \mid p^\alpha$. Because $(m', p^\alpha) = 1$, as $e_1 e_2^2 e_3$ runs over decompositions of m , $c_1 c_2^2 c_3$ and $d_1 d_2^2 d_3$ run over decompositions of m' and p^α respectively. Moreover, as $e_1 e_2$ runs over the divisors of d_1 so does $c_1 d_1 c_2 d_2$. These facts combined with multiplicativity of the Möbius function gives

$$\begin{aligned}
a(m, d) &= \sum_{\substack{e_1 e_2^2 e_3 = m \\ e_1 e_2 \mid d_1 \\ (d_0, e_1 e_3) = 1}} \mu(e_1) e_2 \\
&= \sum_{\substack{c_1 c_2^2 c_3 = m' \\ d_1 d_2^2 d_3 = p^\alpha \\ c_1 d_1 c_2 d_2 \mid d_1 \\ (d_0, c_1 d_1 c_3 d_3) = 1}} \mu(c_1) (d_1) |c_2| d_2 \\
&= \left(\sum_{\substack{c_1 c_2^2 c_3 = m' \\ c_1 c_2 \mid d_1 \\ (d_0, c_1 c_3) = 1}} \mu(c_1) |c_2| \right) \left(\sum_{\substack{d_1 d_2^2 d_3 = p^\alpha \\ d_1 d_2 \mid d_1 \\ (d_0, d_1 d_3) = 1}} \mu(d_1) d_2 \right) \\
&= a(m', d) a(p^\alpha, d),
\end{aligned}$$

as desired. Now we prove multiplicativity in d . Since we have already proven multiplicativity in m , we may assume $m = p^\alpha$. Letting $d = d' p^\beta$, we must show

$$a(p^\alpha, d) = a(p^\alpha, p^\beta).$$

As $e_1 e_2^2 e_3 = p^\alpha$, the e_i are powers of p for $1 \leq i \leq 3$. It follows that $e_1 e_2 \mid d_1$ is equivalent to $e_1 e_2 \mid p^\beta$. Moreover, $(d_0, e_1 e_2) = 1$ is equivalent to $(1, e_1 e_2) = 1$ or $(p, e_1 e_2) = 1$ depending on if β is even or odd. These facts imply the desired identity. \square

The correction polynomials $Q_{d_0 d_1^2}(s, \chi_{a_1})$ are tightly connected to the weighting coefficients $a(m, d)$. In particular, $Q_{d_0 d_1^2}(s, \chi_{a_1})$ is a Dirichlet polynomial whose coefficients are essentially given by the weighting coefficients. We first prove this relationship when d is an odd prime power:

Lemma 1.1. *For any prime p and $\alpha \geq 1$, we have*

$$Q_{p^{2\alpha+1}}(s) = \sum_{k \leq 2\alpha} \frac{a(p^k, p^{2\alpha+1})}{p^{ks}}.$$

Proof. Expanding the correction polynomial in p^{-s} yields

$$Q_{p^{2\alpha+1}}(s) = \sum_{e_1 e_2 \mid p^\alpha} \mu(e_1) \chi_p(e_1) e_1^{-s} e_2^{1-2s} = \sum_{k \leq 2\alpha} \frac{b(p^k, p^{2\alpha+1})}{p^{ks}},$$

where

$$b(p^k, p^{2\alpha+1}) = \sum_{e_1 e_2^2 = p^k} \mu(e_1) \chi_p(e_1) e_2.$$

The proof will be finished if we can show $b(p^k, p^{2\alpha+1}) = a(p^k, p^{2\alpha+1})$. To see this, first observe $\mu(e_1) \chi_p(e_1) = 0$ unless $e_1 = 1$ in which case it is 1. So $b(p^k, p^{2\alpha+1}) = 0$ if k is odd and $p^{\frac{k}{2}}$ if k is even. Compactly stated,

$$b(p^k, p^{2\alpha+1}) = \begin{cases} p^{\frac{k}{2}} & \text{if } k \text{ is even,} \\ 0 & \text{if } k \text{ is odd.} \end{cases}$$

On the other hand, $k \leq \alpha$ so that

$$a(p^k, p^{2\alpha+1}) = \sum_{\substack{e_1 e_2^2 e_3 = p^k \\ e_1 e_2 | p^\alpha \\ (p, e_1 e_3) = 1}} \mu(e_1) e_2 = \sum_{\substack{e_1 e_2^2 | p^k \\ (p, e_1 e_3) = 1}} \mu(e_1) e_2 = \sum_{e_2^2 = p^k} e_2 = \begin{cases} p^{\frac{k}{2}} & \text{if } k \text{ is even,} \\ 0 & \text{if } k \text{ is odd.} \end{cases}$$

This finishes the proof. \square

There is an analogous statement when d is an even prime power up to a square-free factor and relatively prime factor:

Lemma 1.2. *For any square-free integer $d_0 \geq 1$, $a_1 \in \{\pm 1, \pm 2\}$, prime p not dividing d_0 , and $\beta \geq 1$, we have*

$$Q_{d_0 p^{2\beta}}(s, \chi_{a_1}) = (1 - \chi_{a_1 d_0}(p) p^{-s}) \sum_{k \leq 2\beta} \frac{\chi_{a_1 d_0}(p^k) a(p^k, p^{2\beta})}{p^{ks}}.$$

Moreover, the same holds if χ is replaced with $\tilde{\chi}$.

Proof. Expand the correction polynomial in p^{-s} to get

$$Q_{d_0 p^{2\beta}}(s, \chi_{a_1}) = \sum_{e_1 e_2 | p^\alpha} \mu(e_1) \chi_{a_1 d_0}(e_1) e_1^{-s} e_2^{1-2s} = \sum_{k \leq 2\beta} \frac{b(p^k, p^{2\beta})}{p^{ks}}.$$

where

$$b(p^k, p^{2\beta}) = \sum_{e_1 e_2^2 = p^k} \mu(e_1) \chi_{a_1 d_0}(e_1) e_2.$$

It suffices to show $b(p^k, p^{2\beta}) = \chi_{a_1 d_0}(p^k) (a(p^k, p^{2\beta}) - a(p^{k-1}, p^{2\beta}))$. On the one hand, $\mu(e_1) = 0$ unless $e_1 = 1, p$ in which case $\mu(e_1) = \pm 1$ accordingly. So

$$b(p^k, p^{2\beta}) = \sum_{e_1 e_2^2 = p^k} \mu(e_1) \chi_{a_1 d_0}(e_1) e_2 = \begin{cases} \chi_{a_1 d_0}(p^k) p^{\frac{k}{2}} & \text{if } k \text{ is even,} \\ -\chi_{a_1 d_0}(p^k) p^{\frac{k-1}{2}} & \text{if } k \text{ is odd,} \end{cases}$$

where we have used the identity $\chi_{a_1 d_0}(e_1) = \chi_{a_1 d_0}(p^k)$ which holds because this quadratic Dirichlet character only depends upon the parity of k . On the other hand, as in the proof of Lemma 1.1

$$a(p^k, p^{2\beta}) = \begin{cases} p^{\frac{k}{2}} & \text{if } k \text{ is even,} \\ 0 & \text{if } k \text{ is odd.} \end{cases}$$

But then

$$\chi_{a_1 d_0}(p^k) (a(p^k, p^{2\beta}) - a(p^{k-1}, p^{2\beta})) = \begin{cases} \chi_{a_1 d_0}(p^k) p^{\frac{k}{2}} & \text{if } k \text{ is even,} \\ -\chi_{a_1 d_0}(p^k) p^{\frac{k-1}{2}} & \text{if } k \text{ is odd,} \end{cases}$$

which completes the proof as it is obvious that the same holds if χ is replaced with $\tilde{\chi}$. \square

Lemmas 1.1 and 1.2 together show that $Q_{d_0 d_1^2}(s, \chi_{a_1})$ is a Dirichlet polynomial whose coefficients are essentially given by the weighting coefficients $a(m, d)$ when d is an prime power. The proof of these lemmas also give the value of $a(p^k, p^l)$ and we collect this as a corollary:

Corollary 1.1. *For any prime p ,*

$$a(p^k, p^l) = \begin{cases} \min\left(p^{\frac{k}{2}}, p^{\frac{l}{2}}\right) & \text{if } \min(k, l) \text{ is even,} \\ 0 & \text{otherwise.} \end{cases}$$

If we combine Proposition 1.1 and Corollary 1.1 we can compute $a(m, d)$ in general:

Corollary 1.2. *For any integers $d, m \geq 1$,*

$$a(m, d) = \begin{cases} (m, d)^{\frac{1}{2}} & \text{if } (m, d) \text{ is a perfect square,} \\ 0 & \text{otherwise.} \end{cases}$$

As an immediate consequence of Corollary 1.2, $a(m, d)$ is symmetric in m and d . As the weighting coefficients are multiplicative, $Q_{d_0 d_1^2}(s, \chi_{a_1})$ will possess an Euler product. To state the Euler product explicitly, we write $d = d_0 d_1^2 d_2^2$ with d_0 square-free and, d_2 relatively prime to $d_0 d_1$, and such that every prime divisor of d_1 divides d_0 . In other words, d_0 is the square-free part of d , d_1 is the square part of d whose prime factors divide d to odd power, and d_2 is the square part of d whose prime factors divide d to even power. We have the following Euler product:

Theorem 1.4. *Let $d = d_0 d_1^2 d_2^2$ be the square decomposition of d stratified by even and odd powers. Then for any $a_1 \in \{\pm 1, \pm 2\}$,*

$$Q_{d_0 d_1^2 d_2^2}(s, \chi_{a_1}) = \prod_{p^\alpha || d_1} Q_{p^{2\alpha+1}}(s) \cdot \prod_{p^\beta || d_2} Q_{d_0 p^{2\beta}}(s, \chi_{a_1}).$$

Moreover, the same holds if χ is replaced with $\tilde{\chi}$.

Proof. Recall that

$$L(s, \chi_{a_1 d}) = L(s, \chi_{a_1 d_0}) Q_{d_0 d_1^2 d_2^2}(s, \chi_{a_1}) = \sum_{m \geq 1} \frac{\chi_{a_1 d_0}(\widehat{m}) a(m, d)}{m^s}.$$

We will now derive an alternate expression for $L(s, \chi_{a_1 d})$. By Proposition 1.1, the coefficients of $L(s, \chi_{a_1 d})$ are multiplicative. Therefore $L(s, \chi_{a_1 d})$ admits the Euler product

$$L(s, \chi_{a_1 d}) = \prod_{p \text{ prime}} \left(\sum_{k \geq 0} \frac{\chi_{a_1 d_0}(\widehat{p^k}) a(p^k, d)}{p^{ks}} \right).$$

Decomposing the product according to primes dividing $d = d_0 d_1^2 d_2^2$, we get

$$\begin{aligned} & L(s, \chi_{a_1 d}) \\ &= \prod_{p \text{ prime}} \left(\sum_{k \geq 0} \frac{\chi_{a_1 d_0}(\widehat{p^k}) a(p^k, d)}{p^{ks}} \right) \\ &= \prod_{p \nmid d} \left(\sum_{k \geq 0} \frac{\chi_{a_1 d_0}(\widehat{p^k}) a(p^k, 1)}{p^{ks}} \right) \prod_{p^\alpha || d_1} \left(\sum_{k \geq 0} \frac{\chi_{a_1 d_0}(\widehat{p^k}) a(p^k, p^{2\alpha+1})}{p^{ks}} \right) \cdot \prod_{p^\beta || d_2} \left(\sum_{k \geq 0} \frac{\chi_{a_1 d_0}(\widehat{p^k}) a(p^k, p^\beta)}{p^{ks}} \right) \\ &= \prod_{p \nmid d} \left(\sum_{k \geq 0} \frac{\chi_{a_1 d_0}(\widehat{p^k})}{p^{ks}} \right) \prod_{p^\alpha || d_1} \left(\sum_{k \geq 0} \frac{\chi_{a_1 d_0}(\widehat{p^k}) a(p^k, p^{2\alpha+1})}{p^{ks}} \right) \cdot \prod_{p^\beta || d_2} \left(\sum_{k \geq 0} \frac{\chi_{a_1 d_0}(\widehat{p^k}) a(p^k, p^\beta)}{p^{ks}} \right) \\ &= \prod_{p \nmid d} \left(\sum_{k \geq 0} \frac{\chi_{a_1 d_0}(\widehat{p^k})}{p^{ks}} \right) \prod_{p^\alpha || d_1} \left(\sum_{k \geq 0} \frac{a(p^k, p^{2\alpha+1})}{p^{ks}} \right) \cdot \prod_{p^\beta || d_2} \left(\sum_{k \geq 0} \frac{\chi_{a_1 d_0}(p^k) a(p^k, p^\beta)}{p^{ks}} \right). \end{aligned}$$

Including the factors corresponding to primes $p \mid d_2$ into the first product, we must multiply the last factor by the inverse of $\sum_{k \geq 0} \chi_{a_1 d_0}(p) p^{-ks} = (1 - \chi_{a_1 d_0}(p) p^{-s})^{-1}$ obtaining

$$\prod_{p \nmid d_0} \left(\sum_{k \geq 0} \frac{\chi_{a_1 d_0}(\widehat{p^k})}{p^{ks}} \right) \prod_{p^\alpha || d_1} \left(\sum_{k \geq 0} \frac{a(p^k, p^{2\alpha+1})}{p^{ks}} \right) \cdot \prod_{p^\beta || d_2} \left((1 - \chi_{a_1 d_0}(p) p^{-s}) \sum_{k \geq 0} \frac{\chi_{a_1 d_0}(p^k) a(p^k, p^\beta)}{p^{ks}} \right),$$

as every prime divisor of d_1 divides d_0 . The first product is $L(s, \chi_{a_1 d_0})$. For the second and third products, Remark 1.2 implies that the sums run up to $k \leq 2\alpha$ and $k \leq 2\beta$ respectively. Therefore they are $Q_{p^{2\alpha+1}}(s)$ and $Q_{d_0 p^{2\beta}}(s, \chi_{a_1})$ respectively. It follows that

$$L(s, \chi_{a_1 d}) = L(s, \chi_{a_1 d_0}) \cdot \prod_{p^\alpha \parallel d_1} Q_{p^{2\alpha+1}}(s) \cdot \prod_{p^\beta \parallel d_2} Q_{d_0 p^{2\beta}}(s, \chi_{a_1}).$$

This is our alternate expression for $L(s, \chi_{a_1 d})$ and equating the two results in

$$L(s, \chi_{a_1 d_0}) Q_{d_0 d_1^2 d_2^2}(s, \chi_{a_1}) = L(s, \chi_{a_1 d_0}) \cdot \prod_{p^\alpha \parallel d_1} Q_{p^{2\alpha+1}}(s) \cdot \prod_{p^\beta \parallel d_2} Q_{d_0 p^{2\beta}}(s, \chi_{a_1}),$$

from which the proof is complete since $L(s, \chi_{a_1 d_0}) \neq 0$ for $\text{Re}(s) > 1$ (so that we may divide by $L(s, \chi_{a_1 d_0})$) and it is obvious that the same holds if we replace χ with $\tilde{\chi}$. \square

Observe that for $d = d_0 d_1^2 d_2^2$, the prime factors that divide $d_1 d_2$ are exactly those factors that divide d to power larger than 1. Thus, from Theorem 1.4 the Euler product for $Q_{d_0 d_1^2 d_2^2}(s, \chi_{a_1})$ is supported on exactly the primes dividing d to order larger than 1 and also depends upon the character $\chi_{a_1 d_0}$.

FUNCTIONAL EQUATIONS

We can now derive functional equations for $Z_{a_1, a_2}(s, w)$. These functional equations will be induced from the functional equations for $L(s, \chi_{a_1 d})$ and $L(s, \tilde{\chi}_{a_2 m})$. To prove these latter functional equations, we require a functional equation for the correction polynomials:

Theorem 1.5. $Q_{d_0 d_1^2}(s, \chi_{a_1})$ admits the functional equation.

$$Q_{d_0 d_1^2}(s, \chi_{a_1}) = d_1^{1-2s} Q_{d_0 d_1^2}(1-s, \chi_{a_1}).$$

Moreover, the same holds if χ is replaced with $\tilde{\chi}$.

Proof. The strategy is to interchange e_2 and e_3 in the sum defining $Q_{d_0 d_1^2}(s, \chi_{a_1})$:

$$\begin{aligned} d_1^{1-2s} Q_{d_0 d_1^2}(1-s) &= d_1^{1-2s} \sum_{e_1 e_2 e_3 = d_1} \mu(e_1) \chi_{a_1 d_0}(e_1) e_1^{s-1} e_2^{2s-1} \\ &= \sum_{e_1 e_2 e_3 = d_1} \mu(e_1) \chi_{a_1 d_0}(e_1) e_1^{s-1} \left(\frac{d_1}{e_2} \right)^{1-2s} \\ &= \sum_{e_1 e_2 e_3 = d_1} \mu(e_1) \chi_{a_1 d_0}(e_1) e_1^{s-1} (e_1 e_3)^{1-2s} \\ &= \sum_{e_1 e_2 e_3 = d_1} \mu(e_1) \chi_{a_1 d_0}(e_1) e_1^{-s} e_3^{1-2s} \\ &= Q_{d_0 d_1^2}(s, \chi_{a_1}). \end{aligned}$$

Also, it is obvious that the same holds if χ is replaced with $\tilde{\chi}$. \square

We will define the completed L -function $L^*(s, \chi_{a_1 d})$ by

$$L^*(s, \chi_{a_1 d}) = L^*(s, \chi_{a_1 d_0}) Q_{d_0 d_1^2}(s, \chi_{a_1}).$$

In particular, $L^*(s, \chi_d)$ makes sense even when d is not square-free and agrees with the previous definition when d is square-free. Combining Theorem 1.5, the functional equation for $L^*(s, \chi_{a_1 d_0})$, that $\deg(d) \equiv \deg(d_0) \pmod{2}$, and that $d \equiv d_0 \pmod{4}$, we obtain a functional equation for $L^*(s, \chi_{a_1 d})$:

$$L^*(s, \chi_{a_1 d}) = \begin{cases} q(d)^{\frac{1}{2}-s} L^*(1-s, \chi_{a_1 d}) & \text{if } \deg(d) \text{ is even,} \\ q(d)^{\frac{1}{2}-s} L^*(1-s, \chi_{a_1 d}) & \text{if } \deg(d) \text{ is odd.} \end{cases}$$

Analogously, define the completed L -function $L^*(s, \tilde{\chi}_{a_2m})$ by

$$L^*(s, \tilde{\chi}_{a_2m}) = L^*(s, \tilde{\chi}_{a_2m_0})Q_{m_0m_1^2}(s, \tilde{\chi}_{a_2}).$$

Then, as before, we have a functional equation for $L^*(s, \tilde{\chi}_{a_2m})$:

$$L^*(s, \tilde{\chi}_{a_2m}) = \begin{cases} q(m)^{\frac{1}{2}-s} L^*(1-s, \tilde{\chi}_{a_2m}) & \text{if } \deg(m) \text{ is even,} \\ q(m)^{\frac{1}{2}-s} L^*(1-s, \tilde{\chi}_{a_2m}) & \text{if } \deg(m) \text{ is odd.} \end{cases}$$
