

A QUADRATIC DOUBLE DIRICHLET SERIES II: THE NUMBER FIELD CASE

HENRY TWISS

ABSTRACT. We construct a quadratic double Dirichlet series $Z(s, w)$ built from single variable quadratic Dirichlet L -functions $L(s, \chi)$ over \mathbb{Q} . We prove that $Z(s, w)$ admits meromorphic continuation to the (s, w) -plane and satisfies a group of functional equations.

1. PRELIMINARIES

We present an overview of quadratic Dirichlet L -functions over \mathbb{Q} . We begin with the Riemann zeta-function. The zeta function $\zeta(s)$ is defined as the Dirichlet series or Euler product

$$\zeta(s) = \sum_{m \geq 1} \frac{1}{m^s} = \prod_{p \text{ prime}} \left(1 - \frac{1}{p^s}\right)^{-1},$$

for $\operatorname{Re}(s) > 1$. The second equality is an analytic reformulation of the fundamental theorem of arithmetic. The Riemann zeta function also admits meromorphic continuation to \mathbb{C} with a simple pole at $s = 1$ of residue 1. The functional equation is

$$\pi^{-\frac{s}{2}} \Gamma\left(\frac{s}{2}\right) \zeta(s) = \pi^{-\frac{1-s}{2}} \Gamma\left(\frac{1-s}{2}\right) \zeta(1-s).$$

Now we recall characters on \mathbb{Z} . They are multiplicative functions $\chi : \mathbb{Z} \rightarrow \mathbb{C}$ and form a group under multiplication. The two flavors we will care about are:

- Dirichlet characters: multiplicative functions $\chi_d : \mathbb{Z} \rightarrow \mathbb{C}$ modulo $d \geq 1$ (in that they are d -periodic) and such that $\chi_d(m) = 0$ if $(m, d) > 1$.
- Hilbert characters: The group of characters generated by those that appear in the sign change of reciprocity statements.

The image of a Dirichlet character always lands in the roots of unity. Moreover, $\bar{\chi}$ is the multiplicative inverse to χ and the Dirichlet characters modulo d form a subgroup under multiplication. This group is always finite and its order is $\phi(d) = |(\mathbb{F}_q[t]/d\mathbb{F}_q[t])^\times|$. The Dirichlet characters that are of interest to us are those given by the quadratic residue symbol on \mathbb{Z} . First let us recall this symbol. For any odd prime p and any $d \in \mathbb{Z}$, we define the quadratic residue symbol $\left(\frac{d}{p}\right)$ by

$$\left(\frac{d}{p}\right) \equiv d^{\frac{p-1}{2}} \pmod{p} = \begin{cases} 1 & \text{if } x^2 \equiv d \pmod{p} \text{ is solvable,} \\ -1 & \text{if } x^2 \equiv d \pmod{p} \text{ is not solvable,} \\ 0 & \text{if } d \equiv 0 \pmod{p}. \end{cases}$$

This symbol only depends upon d modulo p and is multiplicative in d . We can extend the quadratic residue symbol multiplicatively in the denominator. First we define

$$\left(\frac{d}{-1}\right) = \begin{cases} 1 & \text{if } d \geq 0, \\ -1 & \text{if } d < 0, \end{cases} \quad \text{and} \quad \left(\frac{d}{2}\right) = \begin{cases} 1 & \text{if } d \equiv 1, 7 \pmod{8}, \\ -1 & \text{if } d \equiv 3, 5 \pmod{8}, \\ 0 & \text{if } d \equiv 0 \pmod{2}. \end{cases}$$

If $m = up_1^{e_1}p_2^{e_2}\cdots p_k^{e_k}$ is the prime factorization of m (with $u = \pm 1$), then we define

$$\left(\frac{d}{m}\right) = \left(\frac{d}{u}\right) \prod_{1 \leq i \leq k} \left(\frac{d}{p_i}\right)^{e_i}.$$

The quadratic residue symbol now makes sense for any $m \in \mathbb{Z}$ and is multiplicative in both d and m . The quadratic residue symbol also admits the following reciprocity law:

Theorem 1.1 (Quadratic reciprocity). *If $d, m \in \mathbb{Z}$, then*

$$\left(\frac{d}{m}\right) = (-1)^{\frac{d^{(2)}-1}{2} \frac{m^{(2)}-1}{2}} \left(\frac{m}{|d|}\right),$$

where $d^{(2)}$ and $m^{(2)}$ are the parts of d and m relatively prime to 2 respectively.

Moreover, we have the additional relations

$$\left(\frac{-1}{m}\right) = (-1)^{\frac{m^{(2)}-1}{2}} \quad \text{and} \quad \left(\frac{2}{m}\right) = (-1)^{\frac{m^2-1}{8}},$$

and if $m \not\equiv 0 \pmod{2}$, we can write

$$\left(\frac{-1}{m}\right) = (-1)^{\frac{m-1}{2}} = \begin{cases} 1 & m \equiv 1 \pmod{4}, \\ -1 & m \equiv 3 \pmod{4}, \end{cases} \quad \text{and} \quad \left(\frac{2}{m}\right) = (-1)^{\frac{m^2-1}{8}} = \begin{cases} 1 & m \equiv 1, 7 \pmod{8}, \\ -1 & m \equiv 3, 5 \pmod{8}. \end{cases}$$

We can now define the quadratic Dirichlet characters. For any square-free $d \in \mathbb{Z}$, define the quadratic Dirichlet character χ_d by the following quadratic residue symbol:

$$\chi_d(m) = \begin{cases} \left(\frac{d}{m}\right) & \text{if } d \equiv 1 \pmod{4}, \\ \left(\frac{4d}{m}\right) & \text{if } d \equiv 2, 3 \pmod{4}. \end{cases}$$

This quadratic Dirichlet character is attached to the quadratic extension $\mathbb{Q}(\sqrt{d})$. We extend χ_d multiplicatively in the denominator so that χ_d makes sense for any odd d . In particular, $\chi_d(m) = \pm 1$ provided d and m are relatively prime and $\chi_d(m) = 0$ if $(m, d) > 1$. Quadratic reciprocity implies that χ_d is a Dirichlet character modulo $|d|$ if $d \equiv 1 \pmod{4}$ and is a Dirichlet character modulo $|4d|$ if $d \equiv 2, 3 \pmod{4}$. Indeed, if $d \equiv 1 \pmod{4}$ then $d^{(2)} = d$ and the sign is always 1. If $d \equiv 3 \pmod{4}$, then $d^{(2)} = d$ and the sign is $\left(\frac{-1}{m}\right)$ which is a character modulo 4. If $d \equiv 2 \pmod{4}$, then $d^{(2)} \equiv 1, 3 \pmod{4}$ and we are reduced to one of the previous two cases. We will also set

$$q(d) = \begin{cases} |d| & \text{if } d \equiv 1 \pmod{4}, \\ |4d| & \text{if } d \equiv 2, 3 \pmod{4}, \end{cases} \quad \text{and} \quad \varepsilon_\chi = \frac{\tau(\chi_d)}{\sqrt{q(d)}},$$

where $\tau(\chi_d)$ is the Gauss sum attached to χ_d . We will also require an associated character. For each χ_m (here we are purposely interchanging the roles of d and m to keep consistency with the notation when discussing the quadratic double Dirichlet series later), we define $\tilde{\chi}_m$ by

$$\tilde{\chi}_m(d) = (-1)^{\frac{m^{(2)}-1}{2} \frac{d^{(2)}-1}{2}} \chi_m(d).$$

By quadratic reciprocity, $\tilde{\chi}_m$ is a quadratic Dirichlet character of the same modulus as χ_m and is multiplicative in m . We now discuss the Hilbert characters. We will only need four of them: the quadratic

Dirichlet characters modulo 8. They are given as follows:

$$\begin{aligned}\chi_1(m) &= \begin{cases} 1 & \text{if } m \not\equiv 0 \pmod{2}, \\ 0 & \text{if } m \equiv 0 \pmod{2}, \end{cases} & \chi_{-1}(m) &= \begin{cases} 1 & \text{if } m \equiv 1 \pmod{4}, \\ -1 & \text{if } m \equiv 3 \pmod{4}, \\ 0 & \text{if } m \equiv 0 \pmod{2}, \end{cases} \\ \chi_2(m) &= \begin{cases} 1 & \text{if } m \equiv 1, 7 \pmod{8}, \\ -1 & \text{if } m \equiv 3, 5 \pmod{8}, \\ 0 & \text{if } m \equiv 0 \pmod{2}, \end{cases} & \chi_{-2}(m) &= \begin{cases} 1 & \text{if } m \equiv 1, 3 \pmod{8}, \\ -1 & \text{if } m \equiv 5, 7 \pmod{8}, \\ 0 & \text{if } m \equiv 0 \pmod{2}. \end{cases}\end{aligned}$$

In general, we will denote a Hilbert character by χ_a with $a \in \{\pm 1, \pm 2\}$. The Hilbert characters also satisfy an important orthogonality property:

Theorem 1.2 (Orthogonality of Hilbert characters). *If $d, m \in \mathbb{Z}$ are odd, then*

$$\frac{1}{4} \sum_{a \in \{\pm 1, \pm 2\}} \chi_a(dm) = \begin{cases} 1 & \text{if } d \equiv m \pmod{8}, \\ 0 & \text{if } d \not\equiv m \pmod{8}. \end{cases}$$

Also, we have the identities

$$\tilde{\chi}_a(m) = \chi_a(m), \quad \chi_{-1}(m) = \left(\frac{-1}{m}\right), \quad \text{and} \quad \chi_2(m) = \left(\frac{2}{m}\right),$$

and the relations

$$\chi_{-2}(m) = \chi_{-1}(m)\chi_2(m), \quad \chi_1(m) = \chi_{-1}(m)\chi_{-1}(m), \quad \text{and} \quad \chi_{-1}(m) = \chi_2(m)\chi_{-2}(m).$$

We now return to χ_d for square-free d . If $d \equiv 1, 2, 5 \pmod{8}$, then $d^{(2)} \equiv 1 \pmod{4}$ so that the sign in the statement of quadratic reciprocity is 1. If $d \equiv 3, 6, 7 \pmod{8}$, then $d^{(2)} \equiv 3 \pmod{4}$ and the sign is $(-1)^{\frac{m^{(2)}-1}{2}}$. This fact together with the relations for the quadratic characters modulo 8 imply

$$\chi_d(m) = \begin{cases} \chi_m(d) & \text{if } d \equiv 1 \pmod{4}, \\ \chi_{-1}(m)\chi_m(d) & \text{if } d \equiv 3 \pmod{4}, \\ \chi_2(m)\chi_m\left(\frac{d}{2}\right) & \text{if } d \equiv 2 \pmod{8}, \\ \chi_{-2}(m)\chi_m\left(\frac{d}{2}\right) & \text{if } d \equiv 6 \pmod{8}. \end{cases}$$

With the Dirichlet and Hilbert characters introduced, we are ready to discuss the L -functions associated to quadratic Dirichlet characters. We define the L -function $L(s, \chi_d)$ attached to χ_d for square-free d , by a Dirichlet series or Euler product:

$$L(s, \chi_d) = \sum_{m \geq 1} \frac{\chi_d(m)}{m^s} = \prod_{p \text{ prime}} \left(1 - \frac{\chi_d(p)}{p^s}\right)^{-1}.$$

By definition of the quadratic Dirichlet character, $L(s, \chi_d) \ll \zeta(s)$ for $\text{Re}(s) > 1$ so that $L(s, \chi_d)$ is locally absolutely uniformly convergent in this region. $L(s, \chi_d)$ also admits analytic continuation to \mathbb{C} . The completed L -function $L^*(s, \chi_d)$ is defined as

$$L^*(s, \chi_d) = \begin{cases} \pi^{-\frac{s}{2}} \Gamma\left(\frac{s}{2}\right) L(s, \chi_d) & \text{if } d > 0, \\ \pi^{-\frac{s}{2}} \Gamma\left(\frac{s+1}{2}\right) L(s, \chi_d) & \text{if } d < 0, \end{cases}$$

and satisfies the functional equation

$$L^*(s, \chi_d) = \begin{cases} \varepsilon_{\chi_d} q(d)^{\frac{1}{2}-s} L^*(1-s, \chi_d) & \text{if } d > 0, \\ -\varepsilon_{\chi_d} q(d)^{\frac{1}{2}-s} L^*(1-s, \chi_d) & \text{if } d < 0. \end{cases}$$

Note that the gamma factors depend upon the parity of χ_d . This is the root cause of an important technical issue later when deriving functional equations for the quadratic double Dirichlet series. Analogously, the Dirichlet L -function $L(w, \tilde{\chi}_m)$ attached to $\tilde{\chi}_m$ for square-free m is defined by a Dirichlet series or Euler product:

$$L(w, \tilde{\chi}_m) = \sum_{d \geq 1} \frac{\tilde{\chi}_m(d)}{d^w} = \prod_{p \text{ prime}} \left(1 - \frac{\tilde{\chi}_m(p)}{p^w}\right)^{-1}.$$

As for $L(s, \chi_d)$, $L(w, \tilde{\chi}_m) \ll \zeta(w)$ for $\text{Re}(w) > 1$ so that $L(w, \tilde{\chi}_m)$ is locally absolutely uniformly convergent in this region. Moreover, $L(w, \tilde{\chi}_m)$ admits analytic continuation to \mathbb{C} and the completed L -function $L^*(w, \tilde{\chi}_m)$ is defined as

$$L^*(w, \tilde{\chi}_m) = \begin{cases} \pi^{-\frac{w}{2}} \Gamma\left(\frac{w}{2}\right) L(w, \tilde{\chi}_m) & \text{if } m \equiv 1, 2, 5 \pmod{8}, \\ \pi^{-\frac{w}{2}} \Gamma\left(\frac{w+1}{2}\right) L(w, \tilde{\chi}_m) & \text{if } m \equiv 3, 6, 7 \pmod{8}, \end{cases}$$

and satisfies the functional equation

$$L^*(w, \tilde{\chi}_m) = \begin{cases} \varepsilon_{\tilde{\chi}_m} q(m)^{\frac{1}{2}-w} L^*(1-w, \tilde{\chi}_m) & \text{if } m \equiv 1, 2, 5 \pmod{8}, \\ -\varepsilon_{\tilde{\chi}_m} q(m)^{\frac{1}{2}-w} L^*(1-w, \tilde{\chi}_m) & \text{if } m \equiv 3, 6, 7 \pmod{8}. \end{cases}$$

Remark 1.1. The definitions for $L(s, \chi_d)$, $L^*(s, \chi_d)$, $L(w, \tilde{\chi}_m)$, and $L^*(w, \tilde{\chi}_m)$ work perfectly well even when d and m are not square-free (however the functional equations do not hold). We purposely do not define these L -functions, yet, for d and m not necessarily square-free.

THE QUADRATIC DOUBLE DIRICHLET SERIES

We will now define the quadratic double Dirichlet series $Z(s, w)$. For any integer $d \geq 1$, write $d = d_0 d_1^2$ where d_0 is square-free. Equivalently, d_0 is the square-free part of d and $\frac{d}{d_0}$ is a perfect square. The **quadratic double Dirichlet series** $Z(s, w)$ is defined as

$$Z(s, w) = \sum_{d \text{ odd}} \frac{L^{(2)}(s, \chi_{d_0}) Q_{d_0 d_1^2}(s)}{d^w},$$

where $Q_{d_0 d_1^2}(s)$ is the **correction polynomial** defined by

$$Q_{d_0 d_1^2}(s) = \sum_{e_1 e_2 | d_1} \mu(e_1) \chi_{d_0}(e_1) e_1^{-s} e_2^{1-s} = \sum_{e_1 e_2 e_3 = d_1} \mu(e_1) \chi_{d_0}(e_1) e_1^{-s} e_2^{1-s},$$

and μ is the usual Möbius function. For $\text{Re}(s) > 1$, there is the trivial estimate

$$Q_{d_0 d_1^2}(s) \ll \sum_{e_1 e_2 | d_1} 1 \ll \sigma_0(d_1)^2 \ll_{\varepsilon} d_1^{2\varepsilon} \ll_{\varepsilon} d^{\varepsilon},$$

for any $\varepsilon > 0$. As $L(s, \chi_{d_0}) \ll 1$ for $\text{Re}(s) > 1$, $Z(s, w)$ is locally absolutely uniformly convergent in the region $\Lambda = \{(s, w) \in \mathbb{C}^2 : \text{Re}(s) > 1, \text{Re}(w) > 1\}$. It will also be necessary to consider quadratic double Dirichlet series twisted by a pair of Hilbert characters χ_{a_1} and χ_{a_2} . The **quadratic double Dirichlet series** $Z_{a_1, a_2}(s, w)$ twisted by χ_{a_1} and χ_{a_2} is defined as

$$Z_{a_1, a_2}(s, w) = \sum_{d \text{ odd}} \frac{L^{(2)}(s, \chi_{a_1 d_0}) \chi_{a_2}(d) Q_{d_0 d_1^2}(s, \chi_{a_1})}{d^w},$$

where $Q_{d_0 d_1^2}(s, \chi_{a_1})$ is the **correction polynomial** twisted by χ_{a_1} defined by

$$Q_{d_0 d_1^2}(s, \chi_{a_1}) = \sum_{e_1 e_2 | d_1} \mu(e_1) \chi_{a_1 d_0}(e_1) e_1^{-s} e_2^{1-2s} = \sum_{e_1 e_2 e_3 = d_1} \mu(e_1) \chi_{a_1 d_0}(e_1) e_1^{-s} e_2^{1-2s},$$

and μ is the usual Möbius function. By definition of the Hilbert characters, we have the analogous bound $Q_{d_0 d_1^2}(s, \chi_{a_1}) \ll d_\varepsilon$ so that $Z_{a_1, a_2}(s, w)$ converges locally absolutely uniformly in the same region as $Z(s, w)$ does. In particular, $Z(s, w) = Z_{1,1}(s, w)$. We will also require quadratic double Dirichlet series corresponding to the characters $\tilde{\chi}_m$. Analogously writing $m = m_0 m_1^2$, the **quadratic double Dirichlet series** $\tilde{Z}(s, w)$ is defined as

$$\tilde{Z}(w, s) = \sum_{m \text{ odd}} \frac{L^{(2)}(w, \tilde{\chi}_{m_0}) Q_{m_0 m_1^2}(w)}{m^s},$$

where $Q_{d_0 d_1^2}(w)$ is the **correction polynomial** defined by

$$Q_{m_0 m_1^2}(w) = \sum_{e_1 e_2 | m_1} \mu(e_1) \chi_{m_0}(e_1) e_1^{-w} e_2^{1-w} = \sum_{e_1 e_2 e_3 = m_1} \mu(e_1) \chi_{m_0}(e_1) e_1^{-w} e_2^{1-w},$$

and μ is the usual Möbius function. We have the analogous estimate $Q_{m_0 m_1^2}(w) \ll_\varepsilon m^\varepsilon$ and as $L(w, \tilde{\chi}_{m_0}) \ll 1$ for $\text{Re}(s) > 1$, $\tilde{Z}(w, s)$ is locally absolutely uniformly convergent in the same region as $Z(s, w)$. We also need to consider twists by a pair of Hilbert characters $\tilde{\chi}_{a_2}$ and $\tilde{\chi}_{a_1}$. The **quadratic double Dirichlet series** $\tilde{Z}_{a_2, a_1}(w, s)$ twisted by $\tilde{\chi}_{a_2}$ and $\tilde{\chi}_{a_1}$ is defined as

$$\tilde{Z}_{a_2, a_1}(w, s) = \sum_{m \text{ odd}} \frac{L^{(2)}(w, \tilde{\chi}_{a_2} m_0) \tilde{\chi}_{a_1}(m) Q_{m_0 m_1^2}^2(w, \tilde{\chi}_{a_2})}{m^s},$$

where $Q_{m_0 m_1^2}(w, \tilde{\chi}_{a_2})$ is the **correction polynomial** twisted by $\tilde{\chi}_{a_2}$ defined by

$$Q_{m_0 m_1^2}(w, \tilde{\chi}_{a_2}) = \sum_{e_1 e_2 | m_1} \mu(e_1) \tilde{\chi}_{a_2 m_0}(e_1) e_1^{-w} e_2^{1-2w} = \sum_{e_1 e_2 e_3 = m_1} \mu(e_1) \tilde{\chi}_{a_2 m_0}(e_1) e_1^{-w} e_2^{1-2w}.$$

and μ is the usual Möbius function. By definition of the Hilbert characters, we have the analogous bound $Q_{m_0 m_1^2}(w, \tilde{\chi}_{a_2}) \ll_\varepsilon m^\varepsilon$ so that $\tilde{Z}_{a_2, a_1}(w, s)$ converges locally absolutely uniformly in the same region as $\tilde{Z}(w, s)$ does. In particular, $\tilde{Z}(w, s) = \tilde{Z}_{1,1}(w, s)$.

THE INTERCHANGE

As defined, $Z_{a_1, a_2}(s, w)$ is a sum of L -functions, and hence Euler products, in s . We will prove an interchange formula for $Z_{a_1, a_2}(s, w)$ which will show that it can be expressed as a sum of L -functions in w . That is, we want the variables s and w to change places. Precisely:

Theorem 1.3 (Interchange). *Wherever $Z_{a_1, a_2}(s, w)$ converges locally absolutely uniformly,*

$$Z_{a_1, a_2}(s, w) = \sum_{d \text{ odd}} \frac{L^{(2)}(s, \chi_{a_1 d_0}) \chi_{a_2}(d) Q_{d_0 d_1^2}(s, \chi_{a_1})}{d^w} = \sum_{m \text{ odd}} \frac{L^{(2)}(w, \tilde{\chi}_{a_2 m_0}) \tilde{\chi}_{a_1}(m) Q_{m_0 m_1^2}(w, \tilde{\chi}_{a_2})}{m^s}.$$

Proof. Only the second equality needs to be proved. To do this, first expand the L -function $L^{(2)}(s, \chi_{a_1 d_0})$ and polynomial $Q_{d_0 d_1^2}(s, \chi_{a_1})$ to get

$$\begin{aligned} Z(s, w) &= \sum_{d \text{ odd}} \frac{L^{(2)}(s, \chi_{a_1 d_0}) \chi_{a_2}(d) Q_{d_0 d_1^2}(s, \chi_{a_1})}{d^w} \\ &= \sum_{d \text{ odd}} \left(\sum_{m \text{ odd}} \chi_{a_1 d_0}(m) m^{-s} \right) \left(\sum_{e_1 e_2 | d_1} \mu(e_1) \chi_{a_1 d_0}(e_1) e_1^{-s} e_2^{1-2s} \right) \chi_{a_2}(d) d^{-w} \\ &= \sum_{m, d \text{ odd}} \sum_{e_1 e_2 | d_1} \mu(e_1) \chi_{a_2}(d) \chi_{a_1 d_0}(m e_1) e_1^{-s} e_2^{1-2s} m^{-s} d^{-w}. \end{aligned}$$

Now $\chi_{a_1 d_0}(me_1) = 0$ unless $(d_0, me_1) = 1$. We make this restriction on the sum giving

$$\sum_{m, d \text{ odd}} \sum_{\substack{e_1 e_2 | d_1 \\ (d_0, me_1)=1}} \mu(e_1) \chi_{a_2}(d) \chi_{a_1 d_0}(me_1) e_1^{-s} e_2^{1-2s} m^{-s} d^{-w}.$$

Making the change of variables $me_1 \rightarrow m$ yields

$$\sum_{d \text{ odd}} \sum_{\substack{m \text{ odd} \\ e_1 | m}} \sum_{\substack{e_1 e_2 | d_1 \\ (d_0, m)=1}} \mu(e_1) \chi_{a_2}(d) \chi_{a_1 d_0}(m) e_2^{1-2s} m^{-s} d^{-w}.$$

For fixed $d = d_0 d_1^2$ and e_2 , the subsum over m and e_1 is

$$\sum_{\substack{m \text{ odd} \\ e_1 | m}} \sum_{\substack{e_1 | \frac{d_1}{e_2} \\ (d_0, m)=1}} \mu(e_1) \chi_{a_1 d_0}(m) m^{-s} = \sum_{\substack{m \text{ odd} \\ (d_0, m)=1}} \chi_{a_1 d_0}(m) m^{-s} \left(\sum_{e_1 | \left(\frac{d_1}{e_2}, m\right)} \mu(e_1) \right).$$

The inner sum over e_1 of the Möbius function vanishes unless $\left(\frac{d_1}{e_2}, m\right) = 1$ in which case it is 1. Therefore the triple sum above becomes

$$\sum_{m, d \text{ odd}} \sum_{\substack{e_2 | d_1 \\ \left(\frac{d_0 d_1}{e_2}, m\right)=1}} \chi_{a_2}(d) \chi_{a_1 d_0}(m) e_2^{1-2s} m^{-s} d^{-w}.$$

Making the change of variables $d \rightarrow de_2^2$, the condition $\left(\frac{d_0 d_1}{e_2}, m\right) = 1$ becomes $(d_0 d_1, m) = 1$ which is equivalent to $(d, m) = 1$. Moreover, $\chi_{a_2}(de_2^2) = \chi_{a_2}(d)$. Altogether, we obtain

$$\sum_{\substack{m, d \text{ odd} \\ (d, m)=1}} \sum_{e_2} \chi_{a_2}(d) \chi_{a_1 d_0}(m) e_2^{1-2s-2w} m^{-s} d^{-w}.$$

Writing $m = m_0 m_1^2$ analogously as for d , quadratic reciprocity implies $\chi_{d_0}(m) = \tilde{\chi}_m(d_0) = \tilde{\chi}_{m_0}(d)$ where the last equality holds because $(d, m) = 1$ and both d_0 and m_0 differ from d and m respectively by perfect squares. As $\chi_{a_1}(m) = \tilde{\chi}_{a_1}(m)$ and $\chi_{a_2}(d) = \tilde{\chi}_{a_2}(d)$, the previous fact implies $\chi_{a_2}(d) \chi_{a_1 d_0}(m) = \tilde{\chi}_{a_1}(m) \tilde{\chi}_{a_2 m_0}(d)$ and so our expression becomes

$$\sum_{\substack{m, d \text{ odd} \\ (d, m)=1}} \sum_{e_2} \tilde{\chi}_{a_1}(m) \tilde{\chi}_{a_2 m_0}(d) e_2^{1-2s-2w} m^{-s} d^{-w}.$$

But now we can reverse the argument with the roles of d , m , χ_{a_1} , and χ_{a_2} interchanged respectively, but with $\tilde{\chi}_{a_1}$ and $\tilde{\chi}_{a_2}$, to obtain

$$Z(s, w) = \sum_{m \text{ odd}} \frac{L^{(2)}(w, \tilde{\chi}_{a_2 m_0}) \tilde{\chi}_{a_1}(m) Q_{m_0 m_1^2}(w, \tilde{\chi}_{a_2})}{m^s}.$$

□

Note that the interchange is not completely symmetric because of the characters $\tilde{\chi}_{a_2 m_0}$, $\tilde{\chi}_{a_1}$, and $\tilde{\chi}_{a_2}$ in the second expression for $Z_{a_1, a_2}(s, w)$. This is due to the fact that reciprocity is not perfect. In even more general settings the correction polynomials in w need not be equal to those in s .

Remark 1.2. When $a_1 = a_2 = 1$, the interchange implies

$$Z(s, w) = \tilde{Z}(w, s).$$

More generally, the interchange implies the following relations for twisted quadratic double Dirichlet series:

$$Z_{a_1, a_2}(s, w) = \tilde{Z}_{a_2, a_1}(w, s),$$

for $a_1, a_2 \in \{\pm 1, \pm 2\}$.

WEIGHTING TERMS

We will now study the coefficients of $Z_{a_1, a_2}(s, w)$ expanded in s and w . Expanding $L^{(2)}(s, \chi_{a_1 d_0})Q_{d_0 d_1^2}(s, \chi_{a_1})$ in the numerator of $Z_{a_1, a_2}(s, w)$, we can write

$$Z_{a_1, a_2}(s, w) = \sum_{d \text{ odd}} \frac{L^{(2)}(s, \chi_{a_1 d_0}) \chi_{a_2}(d) Q_{d_0 d_1^2}(s, \chi_{a_1})}{d^w} = \sum_{m, d \text{ odd}} \frac{\chi_{a_1 d_0}(\hat{m}) \chi_{a_2}(d) a(m, d)}{m^s d^w},$$

where \hat{m} is the part of m relatively prime to d_0 and the **weighting coefficient** $a(m, d)$ is given by

$$a(m, d) = \sum_{\substack{e_1 e_2^2 e_3 = m \\ e_1 e_2 | d_1 \\ (d_0, e_1 e_3) = 1}} \mu(e_1) e_2.$$

To see this, the coefficient of $m^{-s} d^{-w}$ in the definition of $Z_{a_1, a_2}(s, w)$ is

$$\begin{aligned} \chi_{a_2}(d) \sum_{\substack{e_1 e_2^2 e_3 = m \\ e_1 e_2 | d_1}} \mu(e_1) \chi_{a_1 d_0}(e_1 e_3) e_2 &= \chi_{a_2}(d) \sum_{\substack{e_1 e_2^2 e_3 = m \\ e_1 e_2 | d_1 \\ (d_0, e_1 e_3) = 1}} \mu(e_1) \chi_{a_1 d_0}(e_1 e_3) e_2 \\ &= \chi_{a_1 d_0}(\hat{m}) \chi_{a_2}(d) \sum_{\substack{e_1 e_2^2 e_3 = m \\ e_1 e_2 | d_1 \\ (d_0, e_1 e_3) = 1}} \mu(e_1) e_2 \\ &= \chi_{a_1 d_0}(\hat{m}) \chi_{a_2}(d) a(m, d), \end{aligned}$$

where the first equality holds because $\chi_{d_0}(e_1 e_3) = 0$ unless $(d_0, e_1 e_3) = 1$ and the second equality holds because if $(d_0, e_1 e_3) = 1$, \hat{m} differs from $e_1 e_3$ by a perfect square (the divisors of which belong to (d_0, e_2)) and so $\chi_{d_0}(e_1 e_3) = \chi_{d_0}(\hat{m})$. For completeness, we extend the definition of $a(m, d)$ to all $m, d \geq 1$. In particular, $a(m, d)$ makes sense when m or d may be even.

Remark 1.3. Also, $a(m, d) = 0$ unless $m = e_1 e_2^2 e_3$ with $(d_0, e_1 e_3) = 1$ and $e_1 e_2^2 | d_1$.

We will define $L(s, \chi_{a_1 d})$ to be the Dirichlet series given by

$$L(s, \chi_{a_1 d}) = L(s, \chi_{a_1 d_0}) Q_{d_0 d_1^2}(s, \chi_{a_1}) = \sum_{m \geq 1} \frac{\chi_{a_1 d_0}(\hat{m}) a(m, d)}{m^s}.$$

In particular, $L(s, \chi_d)$ now makes sense for d not necessarily square-free and this definition agrees with the former when d is square-free. Moreover, we have the representation

$$Z_{a_1, a_2}(s, w) = \sum_{d \text{ odd}} \frac{\chi_{a_2}(d) L^{(2)}(s, \chi_{a_1 d})}{d^w}.$$

If we perform the same procedure but with the interchange, we get

$$\tilde{Z}_{a_2, a_1}(w, s) = \sum_{m \text{ odd}} \frac{L^{(2)}(w, \tilde{\chi}_{a_2 m_0}) \tilde{\chi}_{a_1}(m) Q_{m_0 m_1^2}(w, \tilde{\chi}_{a_2})}{m^s} = \sum_{m, d \text{ odd}} \frac{\tilde{\chi}_{a_2 m_0}(\hat{d}) \tilde{\chi}_{a_1}(m) a(d, m)}{m^s d^w},$$

where \widehat{d} is the part of d relatively prime to m_0 . Analogously, we define $L(w, \widetilde{\chi}_{a_2 m})$ to be the Dirichlet series given by

$$L(w, \widetilde{\chi}_{a_2 m}) = L(w, \widetilde{\chi}_{a_2 m_0}) Q_{m_0 m_1^2}(w, \widetilde{\chi}_{a_2}) = \sum_{d \geq 1} \frac{\widetilde{\chi}_{a_2 m_0}(\widehat{d}) a(d, m)}{d^w},$$

so that

$$\widetilde{Z}_{a_2, a_1}(w, s) = \sum_{m \text{ odd}} \frac{\widetilde{\chi}_{a_1}(m) L^{(2)}(w, \widetilde{\chi}_{a_2 m})}{m^s}.$$

We now investigate the structure of the weighting coefficients $a(m, d)$. Their structure controls the majority of the information about both the quadratic double Dirichlet series and the correction polynomials. We first show that the weighting coefficients possess a multiplicativity property:

Proposition 1.1. *We have $a(m, 1) = a(1, d) = 1$ and*

$$a(m, d) = \prod_{\substack{p^\alpha || m \\ p^\beta || d}} a(p^\alpha, p^\beta).$$

Proof. From the definition of the weighting coefficients, $a(m, 1) = a(1, d) = 1$. We will prove multiplicativity in m and then in d . Letting $m = m' p^\alpha$, we must show

$$a(m, d) = a(m', d) a(p^\alpha, d).$$

To accomplish this, for $e_1 e_2^2 e_3 = m$, let $e_1 = c_1 d_1$, $e_2 = c_2 d_2$, and $e_3 = c_3 d_3$ with $c_1, c_2, c_3 \mid m'$ and $d_1, d_2, d_3 \mid p^\alpha$. Because $(m', p^\alpha) = 1$, as $e_1 e_2^2 e_3$ runs over decompositions of m , $c_1 c_2^2 c_3$ and $d_1 d_2^2 d_3$ run over decompositions of m' and p^α respectively. Moreover, as $e_1 e_2$ runs over the divisors of d_1 so does $c_1 d_1 c_2 d_2$. These facts combined with multiplicativity of the Möbius function gives

$$\begin{aligned} a(m, d) &= \sum_{\substack{e_1 e_2^2 e_3 = m \\ e_1 e_2 \mid d_1 \\ (d_0, e_1 e_3) = 1}} \mu(e_1) e_2 \\ &= \sum_{\substack{c_1 c_2^2 c_3 = m' \\ d_1 d_2^2 d_3 = p^\alpha \\ c_1 d_1 c_2 d_2 \mid d_1 \\ (d_0, c_1 d_1 c_3 d_3) = 1}} \mu(c_1) (d_1) |c_2| d_2 \\ &= \left(\sum_{\substack{c_1 c_2^2 c_3 = m' \\ c_1 c_2 \mid d_1 \\ (d_0, c_1 c_3) = 1}} \mu(c_1) |c_2| \right) \left(\sum_{\substack{d_1 d_2^2 d_3 = p^\alpha \\ d_1 d_2 \mid d_1 \\ (d_0, d_1 d_3) = 1}} \mu(d_1) d_2 \right) \\ &= a(m', d) a(p^\alpha, d), \end{aligned}$$

as desired. Now we prove multiplicativity in d . Since we have already proven multiplicativity in m , we may assume $m = p^\alpha$. Letting $d = d' p^\beta$, we must show

$$a(p^\alpha, d) = a(p^\alpha, p^\beta).$$

As $e_1 e_2^2 e_3 = p^\alpha$, the e_i are powers of p for $1 \leq i \leq 3$. It follows that $e_1 e_2 \mid d_1$ is equivalent to $e_1 e_2 \mid p^\beta$. Moreover, $(d_0, e_1 e_2) = 1$ is equivalent to $(1, e_1 e_2) = 1$ or $(p, e_1 e_2) = 1$ depending on if β is even or odd. These facts imply the desired identity. \square

The correction polynomials $Q_{d_0 d_1^2}(s, \chi_{a_1})$ are tightly connected to the weighting coefficients $a(m, d)$. In particular, $Q_{d_0 d_1^2}(s, \chi_{a_1})$ is a Dirichlet polynomial whose coefficients are essentially given by the weighting coefficients. We first prove this relationship when d is an odd prime power:

Lemma 1.1. *For any prime p and $\alpha \geq 1$, we have*

$$Q_{p^{2\alpha+1}}(s) = \sum_{k \leq 2\alpha} \frac{a(p^k, p^{2\alpha+1})}{p^{ks}}.$$

Moreover, the same holds for $Q_{p^{2\alpha+1}}(w)$.

Proof. Expanding the correction polynomial in p^{-s} yields

$$Q_{p^{2\alpha+1}}(s) = \sum_{e_1 e_2 | p^\alpha} \mu(e_1) \chi_p(e_1) e_1^{-s} e_2^{1-2s} = \sum_{k \leq 2\alpha} \frac{b(p^k, p^{2\alpha+1})}{p^{ks}},$$

where

$$b(p^k, p^{2\alpha+1}) = \sum_{e_1 e_2^2 = p^k} \mu(e_1) \chi_p(e_1) e_2.$$

The proof will be finished if we can show $b(p^k, p^{2\alpha+1}) = a(p^k, p^{2\alpha+1})$. To see this, first observe $\mu(e_1) \chi_p(e_1) = 0$ unless $e_1 = 1$ in which case it is 1. So $b(p^k, p^{2\alpha+1}) = 0$ if k is odd and $p^{\frac{k}{2}}$ if k is even. Compactly stated,

$$b(p^k, p^{2\alpha+1}) = \begin{cases} p^{\frac{k}{2}} & \text{if } k \text{ is even,} \\ 0 & \text{if } k \text{ is odd.} \end{cases}$$

On the other hand, $k \leq \alpha$ so that

$$a(p^k, p^{2\alpha+1}) = \sum_{\substack{e_1 e_2^2 e_3 = p^k \\ e_1 e_2 | p^\alpha \\ (p, e_1 e_3) = 1}} \mu(e_1) e_2 = \sum_{\substack{e_1 e_2^2 | p^k \\ (p, e_1 e_3) = 1}} \mu(e_1) e_2 = \sum_{e_2^2 = p^k} e_2 = \begin{cases} p^{\frac{k}{2}} & \text{if } k \text{ is even,} \\ 0 & \text{if } k \text{ is odd.} \end{cases}$$

This finishes the proof. Clearly the same holds for $Q_{p^{2\alpha+1}}(w)$. \square

There is an analogous statement when d is an even prime power up to a square-free factor and relatively prime factor:

Lemma 1.2. *For any square-free integer $d_0 \geq 1$, $a_1 \in \{\pm 1, \pm 2\}$, prime p not dividing d_0 , and $\beta \geq 1$, we have*

$$Q_{d_0 p^{2\beta}}(s, \chi_{a_1}) = (1 - \chi_{a_1 d_0}(p) p^{-s}) \sum_{k \leq 2\beta} \frac{\chi_{a_1 d_0}(p^k) a(p^k, p^{2\beta})}{p^{ks}}.$$

Moreover, the same holds for $Q_{m_0 p^{2\beta}}(w, \tilde{\chi}_{a_2})$.

Proof. Expand the correction polynomial in p^{-s} to get

$$Q_{d_0 p^{2\beta}}(s, \chi_{a_1}) = \sum_{e_1 e_2 | p^\alpha} \mu(e_1) \chi_{a_1 d_0}(e_1) e_1^{-s} e_2^{1-2s} = \sum_{k \leq 2\beta} \frac{b(p^k, p^{2\beta})}{p^{ks}}.$$

where

$$b(p^k, p^{2\beta}) = \sum_{e_1 e_2^2 = p^k} \mu(e_1) \chi_{a_1 d_0}(e_1) e_2.$$

It suffices to show $b(p^k, p^{2\beta}) = \chi_{a_1 d_0}(p^k) (a(p^k, p^{2\beta}) - a(p^{k-1}, p^{2\beta}))$. On the one hand, $\mu(e_1) = 0$ unless $e_1 = 1, p$ in which case $\mu(e_1) = \pm 1$ accordingly. So

$$b(p^k, p^{2\beta}) = \sum_{e_1 e_2^2 = p^k} \mu(e_1) \chi_{a_1 d_0}(e_1) e_2 = \begin{cases} \chi_{a_1 d_0}(p^k) p^{\frac{k}{2}} & \text{if } k \text{ is even,} \\ -\chi_{a_1 d_0}(p^k) p^{\frac{k-1}{2}} & \text{if } k \text{ is odd,} \end{cases}$$

where we have used the identity $\chi_{a_1 d_0}(e_1) = \chi_{a_1 d_0}(p^k)$ which holds because this quadratic Dirichlet character only depends upon the parity of k . On the other hand, as in the proof of Lemma 1.1

$$a(p^k, p^{2\beta}) = \begin{cases} p^{\frac{k}{2}} & \text{if } k \text{ is even,} \\ 0 & \text{if } k \text{ is odd.} \end{cases}$$

But then

$$\chi_{a_1 d_0}(p^k) (a(p^k, p^{2\beta}) - a(p^{k-1}, p^{2\beta})) = \begin{cases} \chi_{a_1 d_0}(p^k) p^{\frac{k}{2}} & \text{if } k \text{ is even,} \\ -\chi_{a_1 d_0}(p^k) p^{\frac{k-1}{2}} & \text{if } k \text{ is odd,} \end{cases}$$

which completes the proof. Clearly the same holds for $Q_{m_0 p^{2\beta}}(w, \tilde{\chi}_{a_2})$. \square

Lemmas 1.1 and 1.2 together show that $Q_{d_0 d_1^2}(s, \chi_{a_1})$ is a Dirichlet polynomial whose coefficients are essentially given by the weighting coefficients $a(m, d)$ when d is an prime power. The proof of these lemmas also give the value of $a(p^k, p^l)$ and we collect this as a corollary:

Corollary 1.1. *For any prime p ,*

$$a(p^k, p^l) = \begin{cases} \min(p^{\frac{k}{2}}, p^{\frac{l}{2}}) & \text{if } \min(k, l) \text{ is even,} \\ 0 & \text{otherwise.} \end{cases}$$

If we combine Proposition 1.1 and Corollary 1.1 we can compute $a(m, d)$ in general:

Corollary 1.2. *For any integers $m, d \geq 1$,*

$$a(m, d) = \begin{cases} (m, d)^{\frac{1}{2}} & \text{if } (m, d) \text{ is a perfect square,} \\ 0 & \text{otherwise.} \end{cases}$$

As an immediate consequence of Corollary 1.2, $a(m, d)$ is symmetric in m and d . As the weighting coefficients are multiplicative, $Q_{d_0 d_1^2}(s, \chi_{a_1})$ will possess an Euler product. To state the Euler product explicitly, we write $d = d_0 d_1^2 d_2^2$ with d_0 square-free and, d_2 relatively prime to $d_0 d_1$, and such that every prime divisor of d_1 divides d_0 . In other words, d_0 is the square-free part of d , d_1 is the square part of d whose prime factors divide d to odd power, and d_2 is the square part of d whose prime factors divide d to even power. We have the following Euler product:

Theorem 1.4. *Let $d = d_0 d_1^2 d_2^2$ be the square decomposition of d stratified by even and odd powers. Then for any $a_1 \in \{\pm 1, \pm 2\}$,*

$$Q_{d_0 d_1^2 d_2^2}(s, \chi_{a_1}) = \prod_{p^\alpha \parallel d_1} Q_{p^{2\alpha+1}}(s) \cdot \prod_{p^\beta \parallel d_2} Q_{d_0 p^{2\beta}}(s, \chi_{a_1}).$$

Moreover, the same holds for $Q_{m_0 m_1^2 m_2^2}(w, \tilde{\chi}_{a_2})$.

Proof. Recall that

$$L(s, \chi_{a_1 d}) = L(s, \chi_{a_1 d_0}) Q_{d_0 d_1^2 d_2^2}(s, \chi_{a_1}) = \sum_{m \geq 1} \frac{\chi_{a_1 d_0}(\widehat{m}) a(m, d)}{m^s}.$$

We will now derive an alternate expression for $L(s, \chi_{a_1 d})$. By Proposition 1.1, the coefficients of $L(s, \chi_{a_1 d})$ are multiplicative. Therefore $L(s, \chi_{a_1 d})$ admits the Euler product

$$L(s, \chi_{a_1 d}) = \prod_{p \text{ prime}} \left(\sum_{k \geq 0} \frac{\chi_{a_1 d_0}(\widehat{p^k}) a(p^k, d)}{p^{ks}} \right).$$

Decomposing the product according to primes dividing $d = d_0 d_1^2 d_2^2$, we get

$$\begin{aligned} L(s, \chi_{a_1 d}) &= \prod_{p \text{ prime}} \left(\sum_{k \geq 0} \frac{\chi_{a_1 d_0}(\widehat{p^k}) a(p^k, d)}{p^{ks}} \right) \\ &= \prod_{p \nmid d} \left(\sum_{k \geq 0} \frac{\chi_{a_1 d_0}(\widehat{p^k}) a(p^k, 1)}{p^{ks}} \right) \prod_{p^\alpha \parallel d_1} \left(\sum_{k \geq 0} \frac{\chi_{a_1 d_0}(\widehat{p^k}) a(p^k, p^{2\alpha+1})}{p^{ks}} \right) \cdot \prod_{p^\beta \parallel d_2} \left(\sum_{k \geq 0} \frac{\chi_{a_1 d_0}(\widehat{p^k}) a(p^k, p^\beta)}{p^{ks}} \right) \\ &= \prod_{p \nmid d} \left(\sum_{k \geq 0} \frac{\chi_{a_1 d_0}(\widehat{p^k})}{p^{ks}} \right) \prod_{p^\alpha \parallel d_1} \left(\sum_{k \geq 0} \frac{\chi_{a_1 d_0}(\widehat{p^k}) a(p^k, p^{2\alpha+1})}{p^{ks}} \right) \cdot \prod_{p^\beta \parallel d_2} \left(\sum_{k \geq 0} \frac{\chi_{a_1 d_0}(\widehat{p^k}) a(p^k, p^\beta)}{p^{ks}} \right) \\ &= \prod_{p \nmid d} \left(\sum_{k \geq 0} \frac{\chi_{a_1 d_0}(\widehat{p^k})}{p^{ks}} \right) \prod_{p^\alpha \parallel d_1} \left(\sum_{k \geq 0} \frac{a(p^k, p^{2\alpha+1})}{p^{ks}} \right) \cdot \prod_{p^\beta \parallel d_2} \left(\sum_{k \geq 0} \frac{\chi_{a_1 d_0}(p^k) a(p^k, p^\beta)}{p^{ks}} \right). \end{aligned}$$

Including the factors corresponding to primes $p \mid d_2$ into the first product, we must multiply the last factor by the inverse of $\sum_{k \geq 0} \chi_{a_1 d_0}(p) p^{-ks} = (1 - \chi_{a_1 d_0}(p) p^{-s})^{-1}$ obtaining

$$\prod_{p \nmid d_0} \left(\sum_{k \geq 0} \frac{\chi_{a_1 d_0}(\widehat{p^k})}{p^{ks}} \right) \prod_{p^\alpha \parallel d_1} \left(\sum_{k \geq 0} \frac{a(p^k, p^{2\alpha+1})}{p^{ks}} \right) \cdot \prod_{p^\beta \parallel d_2} \left((1 - \chi_{a_1 d_0}(p) p^{-s}) \sum_{k \geq 0} \frac{\chi_{a_1 d_0}(p^k) a(p^k, p^\beta)}{p^{ks}} \right),$$

as every prime divisor of d_1 divides d_0 . The first product is $L(s, \chi_{a_1 d_0})$. For the second and third products, Remark 1.3 implies that the sums run up to $k \leq 2\alpha$ and $k \leq 2\beta$ respectively. Therefore they are $Q_{p^{2\alpha+1}}(s)$ and $Q_{d_0 p^{2\beta}}(s, \chi_{a_1})$ respectively. It follows that

$$L(s, \chi_{a_1 d}) = L(s, \chi_{a_1 d_0}) \cdot \prod_{p^\alpha \parallel d_1} Q_{p^{2\alpha+1}}(s) \cdot \prod_{p^\beta \parallel d_2} Q_{d_0 p^{2\beta}}(s, \chi_{a_1}).$$

This is our alternate expression for $L(s, \chi_{a_1 d})$ and equating the two results in

$$L(s, \chi_{a_1 d_0}) Q_{d_0 d_1^2 d_2^2}(s, \chi_{a_1}) = L(s, \chi_{a_1 d_0}) \cdot \prod_{p^\alpha \parallel d_1} Q_{p^{2\alpha+1}}(s) \cdot \prod_{p^\beta \parallel d_2} Q_{d_0 p^{2\beta}}(s, \chi_{a_1}),$$

from which the proof is complete since $L(s, \chi_{a_1 d_0}) \neq 0$ for $\text{Re}(s) > 1$ (so that we may divide by $L(s, \chi_{a_1 d_0})$). Clearly the same holds for $Q_{m_0 m_1^2 m_2^2}(w, \widetilde{\chi}_{a_2})$. \square

Observe that for $d = d_0 d_1^2 d_2^2$, the prime factors that divide $d_1 d_2$ are exactly those factors that divide d to power larger than 1. Thus, from Theorem 1.4 the Euler product for $Q_{d_0 d_1^2 d_2^2}(s, \chi_{a_1})$ is supported on exactly the primes dividing d to order larger than 1 and also depends upon the character $\chi_{a_1 d_0}$.

FUNCTIONAL EQUATIONS

We can now derive functional equations for $Z_{a_1, a_2}(s, w)$. These functional equations will be induced from the functional equations for $L(s, \chi_{a_1 d})$ and $L(s, \widetilde{\chi}_{a_2 m})$. To prove these latter functional equations, we require a functional equation for the correction polynomials:

Theorem 1.5. $Q_{d_0 d_1^2}(s, \chi_{a_1})$ admits the functional equation.

$$Q_{d_0 d_1^2}(s, \chi_{a_1}) = d_1^{1-2s} Q_{d_0 d_1^2}(1-s, \chi_{a_1}).$$

Moreover, the same holds for $Q_{m_0 m_1^2}(w, \tilde{\chi}_{a_2})$.

Proof. The strategy is to interchange e_2 and e_3 in the sum defining $Q_{d_0 d_1^2}(s, \chi_{a_1})$:

$$\begin{aligned} d_1^{1-2s} Q_{d_0 d_1^2}(1-s) &= d_1^{1-2s} \sum_{e_1 e_2 e_3 = d_1} \mu(e_1) \chi_{a_1 d_0}(e_1) e_1^{s-1} e_2^{2s-1} \\ &= \sum_{e_1 e_2 e_3 = d_1} \mu(e_1) \chi_{a_1 d_0}(e_1) e_1^{s-1} \left(\frac{d_1}{e_2}\right)^{1-2s} \\ &= \sum_{e_1 e_2 e_3 = d_1} \mu(e_1) \chi_{a_1 d_0}(e_1) e_1^{s-1} (e_1 e_3)^{1-2s} \\ &= \sum_{e_1 e_2 e_3 = d_1} \mu(e_1) \chi_{a_1 d_0}(e_1) e_1^{-s} e_3^{1-2s} \\ &= Q_{d_0 d_1^2}(s, \chi_{a_1}). \end{aligned}$$

Clearly the same holds for $Q_{m_0 m_1^2}(w, \tilde{\chi}_{a_2})$. □

We will define the completed L -function $L^*(s, \chi_{a_1 d})$ by

$$L^*(s, \chi_{a_1 d}) = L^*(s, \chi_{a_1 d_0}) Q_{d_0 d_1^2}(s, \chi_{a_1}).$$

In particular, $L^*(s, \chi_d)$ makes sense even when d is not square-free and agrees with the previous definition when d is square-free. Combining Theorem 1.5, the functional equation for $L^*(s, \chi_{a_1 d_0})$, and that $d \equiv d_0 \pmod{4}$, we obtain a functional equation for $L^*(s, \chi_{a_1 d})$:

$$L^*(s, \chi_{a_1 d}) = \begin{cases} \varepsilon_{\chi_{a_1 d_0}} q(d)^{\frac{1}{2}-s} L^*(1-s, \chi_{a_1 d}) & \text{if } a_1 d > 0, \\ -\varepsilon_{\chi_{a_1 d_0}} q(d)^{\frac{1}{2}-s} L^*(1-s, \chi_{a_1 d}) & \text{if } a_1 d < 0. \end{cases}$$

Analogously, define the completed L -function $L^*(w, \tilde{\chi}_{a_2 m})$ by

$$L^*(w, \tilde{\chi}_{a_2 m}) = L^*(w, \tilde{\chi}_{a_2 m_0}) Q_{m_0 m_1^2}(w, \tilde{\chi}_{a_2}).$$

Then, as before, we have a functional equation for $L^*(w, \tilde{\chi}_{a_2 m})$:

$$L^*(w, \tilde{\chi}_{a_2 m}) = \begin{cases} \varepsilon_{\tilde{\chi}_{a_2 m_0}} q(m)^{\frac{1}{2}-w} L^*(1-w, \tilde{\chi}_{a_2 m}) & \text{if } a_2 m \equiv 1, 2, 5 \pmod{8}, \\ -\varepsilon_{\tilde{\chi}_{a_2 m_0}} q(m)^{\frac{1}{2}-w} L^*(1-w, \tilde{\chi}_{a_2 m}) & \text{if } a_2 m \equiv 3, 6, 7 \pmod{8}. \end{cases}$$

The functional equations for $L^*(s, \chi_{a_1 d})$ and $L^*(w, \tilde{\chi}_{a_2 m})$ will induce functional equations for $Z_{a_1, a_2}(s, w)$. However, there is an obstruction caused by the gamma factors. Indeed, the gamma factors for $L^*(s, \chi_{a_1 d})$ and $L^*(w, \tilde{\chi}_{a_2 m})$ depend upon $a_1 d$ and $a_2 m$ modulo 8 respectively. To induce functional equations we need these gamma factors to be constant. Orthogonality of the Hilbert characters will allow us to get past this issue. For $b \in \{1, 3, 5, 7\}$, define $Z_{a_1, a_2}^{b_1}(s, w)$ and $\tilde{Z}_{a_2, a_1}^b(w, s)$ by

$$Z_{a_1, a_2}^b(s, w) = \frac{1}{2} \sum_{a \in \{\pm 1, \pm 2\}} \chi_a(b) Z_{a_1, a a_2}(s, w) \quad \text{and} \quad \tilde{Z}_{a_2, a_1}^b(w, s) = \frac{1}{2} \sum_{a \in \{\pm 1, \pm 2\}} \tilde{\chi}_a(b) \tilde{Z}_{a_2, a a_1}(w, s).$$

In terms of the representations

$$Z_{a_1, a_2}(s, w) = \sum_{d \text{ odd}} \frac{\chi_{a_2}(d) L^{(2)}(s, \chi_{a_1 d})}{d^w} \quad \text{and} \quad \tilde{Z}_{a_2, a_1}(w, s) = \sum_{m \text{ odd}} \frac{\tilde{\chi}_{a_1}(m) L^{(2)}(w, \tilde{\chi}_{a_2 m})}{m^s},$$

and orthogonality of the Hilbert characters, $Z_{a_1, a_2}^{b_1}(s, w)$ and $\tilde{Z}_{a_2, a_1}^b(w, s)$ are subseries containing only those d or m equivalent to b modulo 8 respectively. But then $Z_{a_1, a_2}^{b_1}(s, w)$ and $\tilde{Z}_{a_2, a_1}^b(w, s)$ are sums of L -functions with a fixed gamma factor and so we can obtain functional equations for them. The fact that $Z_{a_1, a_2}(s, w)$ and $\tilde{Z}_{a_2, a_1}(w, s)$ are linear combination of these series respectively will induce function equations. Precisely, we have the following statement:

Theorem 1.6. $Z_{a_1, a_2}(s, w)$ admits the functional equations

$$\text{Todo : } [Z_{a_1, a_2}(s, w) = \varepsilon_{\chi_{a_1 d_0}} \pi^{s - \frac{1}{2}} \frac{\Gamma\left(\frac{1-s}{2}\right)}{\Gamma\left(\frac{s}{2}\right)} \frac{(1 - \chi_{a_1 d}(2)2^{-(1-s)})^{-1}}{(1 - \chi_{a_1 d}(2)2^{-s})^{-1}} Z_{a_1, a_2}\left(1 - s, s + w - \frac{1}{2}\right),]$$

and
